A power converter circuit includes output terminals configured to receive an external voltage. A series circuit with a number of converter units is connected between the output terminals of the power converter circuit. Each converter unit includes input terminals configured to be coupled to a DC power source and output terminals configured to provide an output current. At least one converter unit of the converter units includes a signal generator configured to receive a synchronization signal and to generate a continuous synchronization signal from the synchronization signal. The power converter circuit can be operated in a normal operation mode. In the normal operation mode, the at least one converter unit is configured to regulate generation of the output current such that a frequency and/or a phase of the output current are dependent on the continuous synchronization signal.

POWER CONVERTER CIRCUIT WITH AC OUTPUT

This is a continuation-in-part application of U.S. application Ser. No. 13/352,202, which was filed on Jan. 17, 2012 and is incorporated herein by reference.

TECHNICAL FIELD

Embodiments of the present invention relate to a power converter circuit, a power supply system with a power converter circuit, and a method for operating a power converter circuit.

BACKGROUND

With an increasing interest in sustainable energy production there is a focus on using photovoltaic modules for producing electric power. Photovoltaic (PV) modules include a plurality of photovoltaic (PV) cells, that are also known as solar cells. Since the output voltage of one cell is relatively low, a PV module usually includes a string with a plurality of series connected solar cells, such as between 50 to 100 cells connected in series, or even several such strings connected in parallel.

A PV module provides a DC supply voltage, while power grids, such as national power grids, have an AC supply voltage. In order to supply the energy provided by a PV module to the power grid it is, therefore, necessary to convert the DC voltage of the PV module into an AC voltage that is consistent with the AC supply voltage of the power grid.

A first approach for converting the PV module DC voltage into a power grid AC voltage includes connecting several PV modules in series so as to obtain a DC voltage that is higher than the peak voltage of the power grid AC voltage, and converting the DC voltage into the AC voltage using a DC/AC converter. The amplitude of the DC voltage is typically between 200V and 1000V. High DC voltages, however, are critical in terms of the occurrence of electric arcs.

According to a second approach, a plurality of DC/AC converters are provided, where each of these converters is connected to a PV module. The individual converters have their AC voltage outputs connected in parallel and each of these converters generates an AC voltage that is consistent with the power grid AC supply voltage from the DC voltage provided by the string of solar cells. The DC voltage provided by one PV module usually has an amplitude in the range of between 20V and 100V, depending on the number of cells that are connected in series within one module and depending on the technology used to implement the solar cells, while the peak voltage of the power grid AC voltage is about 155V or 325V, depending on the country. However, due to the large difference between input and output voltages these converters have a disadvantage in terms of efficiency.

According to a further approach, several DC/AC converters are connected in series, where each of these converters receives a DC supply voltage from a PV module. In this system a central control unit is employed to synchronize the individual DC/AC converters in a multi-level switching pattern. This system requires constant synchronized control of all individual units.

There is, therefore, need for a power converter circuit that is capable of efficiently transforming relatively low DC supply voltages into an AC supply voltage that is consistent with a power grid voltage.

SUMMARY OF THE INVENTION

A first aspect relates to a power converter circuit. The power converter circuit includes output terminals configured to receive an external voltage, at least one series circuit with at least two converter units connected between the output terminals of the power converter circuit, each converter unit including input terminals configured to be coupled to a DC power source, output terminals for providing an output current, and a signal generator, and at least one converter unit including a signal generator configured to receive a synchronization signal and configured to generate a continuous synchronization signal from the synchronization signal. The power converter can be operated in a normal operation mode, wherein in the normal mode, the at least one converter unit is configured to regulate a generation of the output current such that at least one of a frequency and a phase of the output current are dependent on the continuous synchronization signal.

A second aspect relates to a power supply system. The power supply system includes output terminals configured to receive an external voltage, at least one series circuit with at least two converter units connected between the output terminals of the power converter circuit, each converter unit including input terminals and output terminals for providing an output current, and at least one converter unit including a signal generator configured to receive a synchronization signal and configured to generate a continuous synchronization signal from the synchronization signal. The power supply system further includes at least two DC power sources, with each DC power source coupled to the input terminals of one converter unit. The power supply system can be operated in a normal operation mode, wherein in the normal mode, the at least one converter unit is configured to regulate a generation of the output current such that at least one of a frequency and a phase of the output current are dependent on the continuous synchronization signal.

BRIEF DESCRIPTION OF THE DRAWINGS

Examples will now be explained with reference to the drawings. The drawings serve to illustrate the basic principle, so that only aspects necessary for understanding the basic principle are illustrated. The drawings are not to scale. In the drawings the same reference characters denote like signals and circuit components.

FIG. 1 schematically illustrates a power converter circuit including a plurality of DC/AC converter units connected in series and a voltage measurement circuit;

FIG. 2 which includes FIGS. 2A-2C illustrates different embodiments of photovoltaic arrays, each including at least one solar cell;

FIG. 3 schematically illustrates a power converter circuit including a plurality of DC/AC converter units connected in series and a voltage measurement circuit including a plurality of measurement units connected in series;

FIG. 4 which includes FIGS. 4A-4D illustrates different embodiments of measurement units;

FIG. 5 shows a block diagram illustrating a first embodiment of one DC/AC converter unit, including a DC/AC converter and a control circuit;

FIG. 6 illustrates an embodiment of the DC/AC converter of FIG. 5 in detail;

FIG. 7 which includes FIGS. 7A to 7C illustrates different embodiments of switches that may be used in the DC/AC converter of FIG. 6;

3

FIG. 8 illustrates a first embodiment of the control circuit of one DC/AC converter unit;

FIG. 9 illustrates a first branch of the control circuit of FIG. 8 in detail;

FIG. 10 illustrates a second embodiment of the control circuit of one DC/AC converter unit;

FIG. 11 shows a block diagram illustrating a second embodiment of one converter unit, including a DC/DC converter, a maximum power point tracker, a DC/AC converter, and a control circuit;

FIG. 12 illustrates an embodiment of the DC/DC converter implemented as a boost converter;

FIG. 13 schematically illustrates a control circuit of the DC/DC converter of FIG. 12;

FIG. 14 illustrates an embodiment of the DC/DC converter implemented as a buck converter;

FIG. 15 illustrates a further embodiment of the control circuit of one DC/AC converter;

FIG. 16 illustrates an embodiment of the DC/DC converter implemented with two interleaved boost converter stages;

FIG. 17 illustrates a first embodiment of a control circuit for the DC/DC converter of FIG. 16;

FIG. 18 illustrates a second embodiment of a control circuit for the DC/DC converter of FIG. 16;

FIG. 19 shows a block diagram illustrating a further embodiment of one DC/AC converter unit including a buck converter and an unfolding bridge;

FIG. 20 shows timing diagrams illustrating the operating principle of the DC/AC converter unit of FIG. 19;

FIG. 21 illustrates a first embodiment of a controller implemented in the DC/AC converter unit of FIG. 19;

FIG. 22 illustrates a second embodiment of a controller implemented in the DC/AC converter unit of FIG. 19;

FIG. 23 illustrates an embodiment of a power converter circuit having a plurality of converter units organized in two series circuits being connected in parallel.

FIG. 24 illustrates a further embodiment of the synchronization circuit.

FIG. 25 illustrates an embodiment of a transmission circuit in the synchronization circuit of FIG. 24.

FIG. 26 illustrates a further embodiment of one converter unit.

FIG. 27 illustrates a first embodiment of a signal generator in the converter unit of FIG. 26.

FIG. 28 illustrates timing diagrams of signals occurring in the signal generator of FIG. 27.

FIG. 29 illustrates a first embodiment of a signal generator in the converter unit of FIG. 26.

FIG. 30 schematically illustrates two possible operation modes of the power converter circuit.

FIG. 31 illustrates an embodiment of a power converter circuit including an operation mode controller.

FIG. 32 illustrates an embodiment of a converter unit including an operation mode unit.

FIG. 33 illustrates a first embodiment of a transfer from a first operation mode to a second operation mode.

FIG. 34 illustrates a second embodiment of a transfer from a first operation mode to a second operation mode.

FIG. 35 illustrates a further embodiment of a power converter circuit.

FIG. 36 illustrates an embodiment of a converter unit implemented in the power converter circuit of FIG. 35.

DETAILED DESCRIPTION OF ILLUSTRATIVE EMBODIMENTS

In the following detailed description, reference is made to the accompanying drawings, which form a part thereof, and

4

in which is shown by way of illustration specific embodiments in which the invention may be practiced. In this regard, directional terminology, such as "top," "bottom," "front," "back," "leading," "trailing," etc., is used with reference to the orientation of the figures being described. Because components of embodiments can be positioned in a number of different orientations, the directional terminology is used for purposes of illustration and is in no way limiting. It is to be understood that other embodiments may be utilized and structural or logical changes may be made without departing from the scope of the present invention. The following detailed description, therefore, is not to be taken in a limiting sense, and the scope of the present invention is defined by the appended claims. It is to be understood that the features of the various exemplary embodiments described herein may be combined with each other, unless specifically noted otherwise.

In the following, embodiments of the present invention will be explained in a specific context, namely in the context of converting electrical power or electrical voltages provided by a plurality of photovoltaic arrays into an AC voltage, specifically an AC power grid supply voltage. However, this is only an example, embodiments of the invention may be employed in a wide range of applications in which a conversion of DC voltages into an AC voltage is required. Any type of DC power source may be used instead of a photovoltaic array, such as a fuel cell. It is even possible, to employ DC power source of different types, such as photovoltaic arrays and fuel cells, in one application.

FIG. 1 illustrates a first embodiment of a power converter circuit (power inverter circuit) 4 for converting a plurality of n (at least two) DC input voltages $V_{3_1}, V_{3_2}, V_{3_n}$ into one AC output voltage v_1 . It should be noted in this connection that throughout the drawings DC voltages and DC currents will be denoted using capital letters "V" and "I", while AC voltages and AC currents will be denoted using lowercase letters "v" and "i". The power converter circuit includes a plurality of n (at least two) converter units $2_1, 2_2, 2_n$, with $n \geq 2$. Each of these converter units includes input terminals $21_1, 22_1; 21_2, 22_2; \text{ and } 21_n, 22_n$, that are configured to be coupled to a DC power source $3_1, 3_2, 3_n$. In FIG. 1, besides the power converter circuit 1 with the converter units $2_1, 2_2, 2_n$, DC power sources $3_1, 3_2, 3_n$ are also illustrated. These DC power sources $3_1, 3_2, 3_n$ together with the power converter circuit 1 form an AC power supply system or an AC current supply system. The DC power sources $3_1, 3_2, 3_n$ are implemented as photovoltaic (PV) modules in the embodiment illustrated in FIG. 1. However employing PV modules as DC power source, such as a power source including fuel cells, may be used as well. It is even possible to employ different types of DC power sources in one power supply system.

Each of the converter units $2_1, 2_2, 2_n$ further includes output terminals $23_1, 24_1; 23_2, 24_2; \text{ and } 23_n, 24_n$. The converter units $2_1, 2_2, 2_n$ are connected in series (in cascade) between output terminals 11, 12 of the power converter circuit 1. For this, a first converter unit 2_1 has a first output terminal 23_1 coupled to a first output terminal 11 of the power converter circuit 1 and a last converter unit 2_n in the cascade has a second output terminal 24_n coupled to a second output terminal 12 of the power converter circuit 1. Further, each of the first output terminals (other than output terminal 23_1) are connected to one second output terminal (other than output terminal 24_n) of another converter unit.

The output terminals 11, 12 of the power converter circuit 1 are configured to receive a voltage v_1 . For example, the output terminals 11, 12 are configured to be connected to a

5

power grid, so that the external voltage v_1 corresponds to a grid voltage or, more specifically, corresponds to one phase of the power grid. In FIG. 1, the power grid is represented by a voltage source **100** and a load Z connected in parallel with the power source **100**. The voltage source **100** of the power grid represents a plurality of AC voltage sources in the power grid, and load Z represents a plurality of loads connected to the power sources in the power grid. The power grid defines the AC voltage v_1 between the output terminal. Since this voltage v_1 is defined by an external source, such as the power grid, this voltage will be referred to as external AC voltage v_1 in the following.

Each of the converter units $2_1, 2_2, 2_n$ provides an AC output voltage $v_{2_1}, v_{2_2}, v_{2_n}$ between its output terminals **23₁, 24₁, 23₂, 24₂, 23_n, 24_n**. By having the converter units $2_1, 2_2, 2_n$ connected in series, the sum of the individual AC output voltages $v_{2_1}, v_{2_2}, v_{2_n}$ of the converter units $2_1, 2_2, 2_n$ corresponds to the external voltage v_1 when the power converter circuit **1** is in the steady state, that is,

$$v_1 = \sum_{i=1}^n v_{2_i}. \quad (1)$$

Each power converter unit $2_1, 2_2, 2_n$ further includes an output capacitance C_1, C_2, C_n connected between the individual output terminals **23₁, 24₁, 23₂, 24₂, 23_n, 24_n** and provides an output current $i_{1_1}, i_{1_2}, i_{1_n}$. The output current of one converter unit $2_1, 2_2, 2_n$ is the current received at a circuit node common to the output capacitance C_1, C_2, C_n and one of the output terminals. For example, in the first converter unit 2_1 , the output current of the converter unit 2_1 is the current flowing into the circuit node at which the output capacitor C_1 is connected to the first output terminal **23₁**. The current flowing from the first output terminal **23₁** of the first converter unit 2_1 will be referred to as converter circuit output current i_{OUT} . This current corresponds to the current flowing between the individual converter units 2_1-2_n . The output capacitances C_1, C_2, C_n are part of the individual converter units $2_1, 2_2, 2_n$ and can be implemented in many different ways as will be explained with reference to several examples herein below.

In the steady state, the AC output currents $i_{1_1}, i_{1_2}, i_{1_n}$ or, more precisely, the rms values of the AC output currents $i_{1_1}, i_{1_2}, i_{1_n}$, correspond to the power converter circuit output current i_{OUT} or the rms value of the output current i_{OUT} , respectively, so that there is very little to no rms current into the output capacitors C_1-C_n . However, there can be situations in which the output currents $i_{1_1}, i_{1_2}, i_{1_n}$ of the individual converter units $2_1, 2_2, 2_n$ change and in which the output currents $i_{1_1}, i_{1_2}, i_{1_n}$ are mutually different until the system has settled at new (equal) output currents $i_{1_1}, i_{1_2}, i_{1_n}$. This is explained in further detail below.

The power converter circuit **1** further includes a synchronization circuit **10** connected between the output terminals **11, 12** of the power converter circuit **1**. The synchronization circuit **10** is configured to provide at least one synchronization signal S_{v_1} . According to one embodiment, the synchronization signal is an AC signal having a phase and a frequency that are dependent on the phase and the frequency, respectively, of the external AC voltage v_1 .

The individual converter units $2_1, 2_2, 2_n$ are each configured to receive one synchronization signal S_{v_1} . In the embodiment illustrated in FIG. 1, the individual converter units $2_1, 2_2, 2_n$ receive the same synchronization signal S_{v_1} . However, this is only an example. It is also possible to

6

generate one synchronization signal for each of the converter units $2_1, 2_2, 2_n$. An embodiment is explained with reference to FIG. 3 herein below. The at least one synchronization signal S_{v_1} can be transmitted to the individual converter units $2_1, 2_2, 2_n$ in different ways. Referring to FIG. 1, a signal transmission bus can be provided through which the at least one synchronization signal S_{v_1} is transmitted to the individual converter units $2_1, 2_2, 2_n$. According to a further embodiment (not illustrated in FIG. 1), there is a dedicated transmission path between the voltage synchronization circuit **10** and each of the converter units $2_1, 2_2, 2_n$. The signal transmission bus or the signal transmission paths can be implemented like conventional signal transmission buses or like conventional signal transmission paths. The signal bus or the signal paths may include level shifter or other means to transmit the at least one synchronization signal from the synchronization circuit **10** to the individual converter units $2_1, 2_2, 2_n$ that (due to being connected in series) have different reference potentials or different voltage domains.

The individual converter units $2_1, 2_2, 2_n$ each include at least one internal control loop which will be explained in further detail herein below. The control loop of each converter unit $2_1, 2_2, 2_n$ is configured to have each converter unit $2_1, 2_2, 2_n$ generate the corresponding output current $i_{1_1}, i_{1_2}, i_{1_n}$ such that there is a given phase difference between the phase as represented by the at least one synchronization signal S_{v_1} , and the phase of its AC output current $i_{1_1}, i_{1_2}, i_{1_n}$. According to one embodiment, the synchronization signal S_{v_1} is in phase with the external AC voltage v_1 and the individual output currents $i_{1_1}, i_{1_2}, i_{1_n}$ are generated to be in phase with the synchronization signal S_{v_1} and, therefore, the external AC voltage v_1 , so that the phase difference is zero. According to another embodiment, the phase difference is not zero. When setting the difference to a value other than zero, reactive power is fed into the power grid. This may help to stabilize the external AC voltage, which is e.g. a power grid.

In FIG. 1, same features of the DC voltage sources **3₁, 3₂, 3_n** have the same reference characters, where the reference characters of the individual DC voltage sources **3₁, 3₂, 3_n** can be distinguished from each other by subscript indices "1", "2", "n". Equivalently, same features of the converter units $2_1, 2_2, 2_n$ have the same reference characters that can be distinguished by subscript indices, "1" for the first converter unit 2_1 , "2" for the second converter unit 2_2 and "n" for the n-th converter unit 2_n . In the following, when explanations equivalently apply to each of the DC sources $2_1, 2_2, 2_n$ or to each of the converter units $2_1, 2_2, 2_n$, reference characters will be used without indices. In the following, reference character **2**, for example, represents an arbitrary one of the converter units, reference character **23** represents a first output terminal of an arbitrary one of the converter units, reference character i_1 denotes the output current of an arbitrary converter unit **2**, reference character C denotes the output capacitance C of an arbitrary converter unit **2**, and so on.

The power converter of FIG. 1 includes $n=3$ converter units **2**. However, having $n=3$ converter units is only an example. Any number of n converter units **2**, wherein $n>1$, can be connected in series to form the power converter circuit **1**.

Besides the internal control loops of the converter units **2** the power converter circuit **1** does not require an outer control loop connected to the individual converter units **2** and/or additional communication paths between the individual converter units **2**, when the power converter circuit **1**

is in the steady state. When the power converter circuit 1 is in the steady state the system can be defined by equation (1) and one further equation for each of the converter units 2:

$$v_{2_RMS} \cdot i_{1_RMS} = V_3 \cdot I_3 \quad (2),$$

where v_{2_RMS} denotes the RMS (route mean square) value of the output voltage v_2 of one converter units 2, i_{1_RMS} denotes the RMS value of the output current i_1 of one converter unit, V_3 denotes the input voltage and I_3 denotes the input current of the converter unit 2. It should be noted that (very low) losses may occur in each converter unit 2. For the sake of simplicity, these losses are not considered in equation (2). In the steady state, the RMS values of the individual output currents i_{1_RMS} are equal and correspond to the rms value of the power converter circuit output current i_{OUT_RMS} , that is:

$$i_{1_RMS} = i_{OUT_RMS} \quad (3)$$

Since equations (2) and (3) is valid for each of the individual converter units, there are n equations, each of these equations describing the relationship between the input power and the average output power of each of the converter units 2, where the input power P_{in} is given as

$$P_{in} = V_3 \cdot I_3 \quad (4),$$

and the output power P_{out} is given as

$$P_{out} = v_{2_RMS} \cdot i_{1_RMS} \quad (5).$$

The input power P_{in} of each of the individual converter units 2 and the input voltage V_3 and the input current I_3 , respectively, are external parameters given by the individual DC power sources 3. The external AC voltage v_1 between the output terminals 11, 12 is defined by the power grid.

Thus, there are $n+1$ variables in the power converter circuit 1, namely the n output voltages v_2 of the individual converter units 2 and the (equal) output currents i_1 . However, referring to equations (1) and (2) the system is defined by $n+1$ equations, so that each of the $n+1$ variables is determined when the system is in its steady state. Besides having each of the converters 2 generate its AC output current i_1 such that there is a given phase difference (such as zero) between the AC output current i_1 and the external AC voltage no additional control or regulation mechanism is required. When the output currents i_1 of the individual converter units 2 are in phase with the external AC voltage v_1 the real output power of each converter unit equals the apparent output power, so that the reactive output power is zero. The individual converter units 2 control their output currents i_1 dependent on the phase information as represented by the at least one synchronization signal S_{v1} and control their output current such that the input power received at the input terminals 21, 22 equals the output power at the output terminals 23, 24.

The DC power sources 3 implemented as PV arrays are only schematically illustrated in FIG. 1. These PV arrays each include at least one solar cell. Some exemplary embodiments of PV arrays including at least one solar cell are illustrated in FIGS. 2A to 2C. FIG. 2A illustrates a first embodiment. In this embodiment, the PV array 3 includes only one solar cell 31. Referring to a further embodiment illustrated in FIG. 2B, one PV array 3 includes a string of m solar cells 31, 3 m_1 , 3 1_p , 3 m_p . Each of the strings includes m solar cells 31, 3 m_1 , 3 1_p , 3 m_p . However, the embodiments illustrated in FIGS. 2A to 2C are only exemplary. Many other solar cell arrangements may be used as well as a DC source 3.

FIG. 3 illustrates an embodiment of a power converter circuit that includes a synchronization circuit 10 implemented as a voltage measurement circuit with a plurality of measurement units 10₁, 10₂, 10_n. The individual measurement units 10₁, 10₂, 10_n are connected in series between the output terminals 11, 12. For simplicity of the illustration, the output capacitances (C_1 - C_n in FIG. 1) are not illustrated in FIG. 3. The plurality of measurement units 10₁, 10₂, 10_n forms a voltage divider, wherein a voltage drop v_{1_1} , v_{1_2} , v_{1_n} across each of the measurement units 10₁, 10₂, 10_n is a function of the external AC voltage v_1 and includes an information on the frequency and the phase of the external AC voltage v_1 . In this embodiment, each converter unit 2₁, 2₂, 2_n has a synchronization input with two input terminals 25₁, 26₁, 25₂, 26₂, 25_n, 26_n, and each converter unit 2₁, 2₂, 2_n has the synchronization input terminals coupled to one measurement unit 10₁, 10₂, 10_n, so as to receive one measurement voltage v_{1_1} , v_{1_2} , v_{1_n} as the synchronization signal.

In the embodiment illustrated in FIG. 3, the number of measurement units 10₁, 10₂, 10_n corresponds to the number of converter units 2₁, 2₂, 2_n, so that each measurement unit 10₁, 10₂, 10_n is associated with one converter unit 2₁, 2₂, 2_n. However, this is only an example. According to a further embodiment (not illustrated) the measurement voltage provided by one measurement unit is received by two or more converter units.

The individual measurement units 10₁, 10₂, 10_n can be implemented in many different ways. Some examples are explained with reference to FIGS. 4A to 4D below. In these FIGS. 4A to 4D, reference character 10, denotes an arbitrary one of the measurement units 10₁, 10₂, 10_n illustrated in FIG. 3.

Referring to FIG. 4A, one measurement unit 10_i may include a resistor 101 connected between the terminals of the measurement unit 10_i that serve to connect the individual measurement units (10₁-10_n in FIG. 3) in series and that serve to couple the individual measurement units to the converter units (2₁-2_n in FIG. 3). According to one embodiment, the resistances of the resistors 101 in the individual measurement units 10_i are equal or at least approximately equal. In this case, the absolute values of the measurement voltages v_{1_i} provided by the individual measurement units 10_i are equal. In a measurement circuit 10 that includes measurement units 10_i implemented with a resistor 101, the individual measurement voltages v_{1_i} are proportional to the output voltage v_1 .

In a measurement circuit 10 with measurement units 10_i including resistors, the individual measurement units 10_i form a resistive voltage divider. Referring to a further embodiment illustrated in FIG. 4B, the individual measurement units 10_i each include a capacitor 102 instead of a resistor. In this case, the individual measurement units 10_i form a capacitive voltage divider between the output terminals 11, 12.

Referring to FIG. 4C, that illustrates a further embodiment, each measurement unit 10_i can be implemented with a parallel circuit including a resistor 101 and a capacitor 102.

Referring to FIG. 4D, that illustrates yet another embodiment of one measurement unit 10_i, each measurement unit or at least some of the measurement units can be implemented with a voltage divider having a first voltage divider 101 and a second voltage divider element 102. These voltage divider elements are implemented as resistors in the embodiment according to FIG. 4D. However, these voltage divider elements 101, 102 could also be implemented as capacitors or as combinations with at least one resistor and at least one

capacitor. In this embodiment, the measurement voltage $v1$, is not the voltage across the measurement unit 10 , but is the voltage across the first voltage divider element 101 , so that the measurement voltage $v1_i$ is a fraction of the voltage across the measurement unit 10 .

It should be noted that implementing the synchronization circuit 10 as a voltage measurement circuit that generates the synchronization signal S_{v1} to be in phase with the external AC voltage $v1$ is only an example. Examples of other synchronization circuits are explained herein further below.

FIG. 5 illustrates a first embodiment of a converter unit 2 for converting the DC input voltage provided by one DC source (not shown in FIG. 3) into an AC output voltage $v2$. The converter unit 2 includes a DC/AC converter 4 connected between the input terminals 23 , 22 and the output terminals 23 , 24 . The DC/AC converter receives the DC voltage $V3$ provided by the DC power source as an input voltage and the DC supply current $I3$ of the DC power source as an input current. The DC/AC converter 4 further receives a reference signal S_{REF} , which may be an alternating signal having a frequency and a phase. The DC/AC converter 4 is configured to generate the AC output current $i1$ dependent on the reference signal S_{REF} such that a frequency and a phase of the output current $i1$ correspond to a frequency and a phase, respectively, of the synchronization signal S_{v1} . The DC/AC converter 4 can be implemented like a conventional DC/AC converter that is configured to generate an output current in phase with an alternating reference signal. Such DC/AC converters are commonly known.

It should be noted that each of the DC/AC converter units 2_1 , 2_2 , 2_n controls its output current $i1$ to have a phase and frequency that is dependent on the at least one synchronization signal S_{v1} .

The reference signal S_{REF} is generated by a control circuit 5 dependent on the synchronization signal S_{v1} and an output current signal S_{i1} . The synchronization signal S_{v1} is either the synchronization signal S_{v1} explained with reference to FIG. 1, one of the measurement voltages $v1_i$ explained with reference to FIG. 3, or a scaled version or a fraction thereof. The output current signal S_{i1} represents the output current $i1$, i.e. the output current signal S_{i1} is dependent on the output current $i1$. According to one embodiment, the output current signal S_{i1} is a scaled version of the output current $i1$. The output current signal S_{i1} can be generated in a conventional manner from the output current $i1$ using a current measurement circuit (not illustrated). The output current signal S_{i1} is generated for each of the converter units (2_1 - 2_n) individually by detecting the respective output current of each converter unit. Referring to FIG. 5, the output current $i1$ of the illustrated converter unit 2 is the current received at the circuit node common to the first output terminal 23 and the output capacitance C .

The control circuit 5 , which will also be referred to as controller in the following, generates the reference signal S_{REF} dependent on the synchronization signal S_{v1} and the output current signal S_{i1} such that the output current, when generated in correspondence with the reference signal S_{REF} , is in phase with the external AC voltage $v1$ or has a given phase shift relative to the external AC voltage $v1$. It should be noted that, since the external AC voltage $v1$ and the output current $i1$ are alternating signals, the synchronization signal S_{v1} and the output current signal S_{i1} are also alternating signals. In the converter unit 2 , the DC/AC converter 4 and the controller 5 are part of a control loop that controls the output current $i1$ to be in phase with the external AC voltage $v1$ or to have a given phase shift relative thereto.

Although a conventional DC/AC converter may be used in the converter unit 2 as the DC/AC converter 4 connected between the input terminals 21 , 22 and the output terminals 23 , 24 , one example of a DC/AC converter 4 will be explained in detail with reference to FIG. 6, in order to ease understanding of embodiments of the invention.

The DC/AC converter 4 illustrated in FIG. 6 is a full-bridge (H4) converter with two half-bridge circuits each connected between the input terminals 21 , 22 . Each of these half-bridge circuits includes two switches each having a load path and a control terminal. The load paths of the two switches of one half-bridge circuit are connected in series between the input terminals 21 , 22 , where a first switch 42_1 and a second switch 42_2 form the first half-bridge, and a third switch 42_3 and a fourth switch 42_4 form the second half-bridge. Each of the half-bridges includes an output, where an output of the first half-bridge is formed by a circuit node common to the load paths of the first and second switch 42_1 , 42_2 . An output of the second half-bridge is formed by a circuit node common to the load paths of the third and fourth switches 42_3 , 42_4 . The output of the first half-bridge is coupled to the first output terminal 23 of the converter unit 2 via a first inductive element 44_1 , such as a choke. The output terminal of the second half-bridge is coupled to the second output terminal 24 of the converter unit 2 via a second inductive element 44_2 , such as a choke. According to a further embodiment (not illustrated) only one of the first and second inductive elements 44_1 , 44_2 is employed. The converter 4 further includes an input capacitance 41 , such as a capacitance, connected between the input terminals 21 , 22 , and the output capacitance C connected between the output terminals 23 , 24 .

Each of the switches 42_1 , 42_2 , 42_3 , 42_4 receives a control signal $S42_1$, $S42_2$, $S42_3$, $S42_4$ at its control terminal. These control signals $S42_1$ - $S42_4$ are provided by a drive circuit 45 dependent on the reference signals S_{REF} received from the controller 5 . The drive signals $S42_1$ - $S42_4$ are pulse-width modulated (PWM) drive signals configured to switch the corresponding switch 42_1 - 42_4 on and off. It should be noted that a switching frequency of the PWM signals $S42_1$ - $S42_4$ is significantly higher than a frequency of the alternating reference signal S_{REF} . The reference signal S_{REF} may be a sinusoidal signal with a frequency of 50 Hz or 60 Hz, depending on the country in which the power grid is implemented, while the switching frequency of the individual switches 42_1 - 42_4 may be in the range of several kHz up to several 10 kHz, or even up to several 100 kHz. The drive circuit 45 is configured to individually adjust the duty cycle of each of the drive signals $S42_1$ - $S42_4$ between 0 and 1 in order to have the waveform of the output current $i1$ follow the waveform of the reference signal S_{REF} . When the duty cycle of one drive signal is 0, the corresponding switch is permanently switched off, and when the duty cycle of one drive signal is 1, the corresponding switch is permanently switched on. The duty cycle of a drive signal is the relationship between the time period for which the drive signal switches the corresponding switch and the duration of one switching cycle. The duration of one switching cycle is the reciprocal of the switching frequency.

Referring to what has been explained before, the output current $i1$ is an AC current with a positive half-cycle in which the output current is positive, and with a negative half-cycle in which the output current $i1$ is negative. The time behavior of the output current $i1$ is dependent on the reference signal S_{REF} which also has positive and negative half-cycles.

11

Two possible operating principles of the converter 4 will briefly be explained. First, it is assumed that a positive half-cycle of the output current i_1 is to be generated. According to a first operating principle, which is known as bipolar switching or 2-level switching, the first and fourth switches 42₁, 42₄ are switched on and off synchronously, while the second and third switches 42₂, 42₃ are permanently switched off. During an on-phase of the first and fourth switches 42₁, 42₄ an output current i_1 is forced through the choke(s) 44₁, 44₂ that is dependent on the voltage difference between the input voltage V_3 across the input capacitance 41 and the output voltage v_2 , where the output voltage v_2 is defined by the power grid voltage v_N . The switches 42₁-42₄ each include a freewheeling element, such as a diode, that is also illustrated in FIG. 4. The freewheeling elements of the second and third switches 42₂, 42₃ take the current flowing through the choke(s) 44₁, 44₂ when the first and fourth switches 42₁, 42₄ are switched off. In this method, the amplitude of the output current i_1 can be adjusted through the duty cycle of the synchronous switching operation of the first and fourth switches 42₁, 42₄. When the switching frequency of the switches 42₁, 42₄ is much higher than the desired frequency of the output current, amplitude, frequency and phase of the AC output current i_1 can be adjusted dependent on the reference signal S_{REF} through the duty cycle of the synchronous switching operation of the first and fourth switches 42₁, 42₄. During the negative half-cycle the second and third switches 42₂, 42₃ are switched on and off synchronously, while the first and fourth switches 42₁, 42₄ are permanently off, so that the body diodes of these first and fourth switches 42₁, 42₄ are conducting. Alternatively, the switches 42₁, 42₄ are switched (with short dead times) when their body diodes are forward biased, so as to be operated as synchronous rectifiers.

According to a second operating principle, which is known as phase chopping or 3-level switching, the first switch 42₁ is permanently switched on during the positive half cycle of the output voltage v_2 , the second and third switches 42₂, 42₃ are permanently off, and the fourth switch 42₄ is switched on and off in a clocked fashion. During an on-phase of the first and fourth switches 42₁, 42₄ an output current i_1 is forced through the choke(s) 44₁, 44₂ that is dependent on voltage difference between the input voltage V_3 across the input capacitance 41 and the output voltage v_2 , where the output voltage v_2 is defined by the power grid voltage v_N . During an off-phase of the fourth switch 42₄ a freewheeling path is offered by the freewheeling element of switch 42₃ and the switched-on first switch 42₁ thus enabling a zero volt state across the output chokes. In this method, the amplitude of the output current i_1 can be adjusted through the duty cycle of the switching operation of the fourth switch 42₁, 42₄. During the negative half-cycle the first and fourth switches 42₁, 42₄ are permanently switched off, the second switch 42₂ is permanently switched on, and the third switch 42₃ is switched on and off in a clocked fashion.

In order to control an instantaneous amplitude of the output current i_1 during the positive half-cycle, the drive circuit 45 varies the duty cycle of the at least one switch that is switched on and off in a clocked fashion. The duty cycle of the at least one clocked switch and the duty cycle of its drive signal, respectively, is increased in order to increase the amplitude of the output current i_1 and is decreased in order to decrease the amplitude of the output current i_1 . This duty cycle is dependent on the instantaneous amplitude of the reference signal S_{REF} .

The switches 42₁-42₄ may be implemented as conventional electronic switches. Referring to FIG. 7A, which

12

illustrates a first embodiment for implementing the switches, the switches may be implemented as MOSFETs, specifically as n-type MOSFETs. Electronic switch 42 in FIG. 7A represents an arbitrary one of the switches 42₁-42₄. A MOSFET, such as the n-type MOSFET illustrated in FIG. 7A has an integrated diode that is also illustrated in FIG. 7A. This diode is known as body diode and may act as a freewheeling element. A drain-source path, which is a path between a drain terminal and a source terminal, forms a load path of a MOSFET, and a gate terminal forms a control terminal.

Referring to FIG. 7B, the switches 42₁-42₄ could also be implemented as IGBTs, where additionally a diode may be connected between a collector and an emitter terminal of the IGBT. This diode acts as a freewheeling element. In an IGBT, the load path runs between the emitter and the collector terminal, and the gate terminal forms a control terminal.

According to a further embodiment, two of the four switches, such as the first and third transistors 42₁, 42₃ are implemented as SCR Thyristors, while the other two switches are implemented as MOSFET.

According to yet another embodiment, illustrated in FIG. 7C, the switches 42₁-42₄ can be implemented as GaN-HEMTs (Gallium-Nitride High Electron Mobility Transistors). Unlike a conventional (silicon or silicon carbide) MOSFET a GaN-HEMT does not include an integrated body diode. In a GaN-HEMT, a current conduction in a reverse direction (corresponding to the forward direction of a body diode in a conventional MOSFET) can be obtained through a substrate biased turn-on. When implementing the switches in GaN technology, all switches of one converter unit can be implemented on a common semiconductor substrate.

FIG. 8 schematically illustrates an embodiment of the controller 5 that generates the reference signal S_{REF} dependent on the synchronization signal S_{v1} and the output current signal S_{i1} . FIG. 8 shows a block diagram of the controller 5 in order to illustrate its operating principle. It should be noted that the block diagram illustrated in FIG. 8 merely serves to illustrate the functionality of the controller 5 rather than its implementation. The individual function blocks, that will be explained in further detail below, may be implemented using a conventional technology that is suitable to implement a controller. Specifically, the function blocks of the controller 5 may be implemented as analog circuits, digital circuits, or may be implemented using hardware and software, such as a microcontroller on which a specific software is running in order to implement the functionality of the controller 5.

Referring to FIG. 8, the controller 5 includes a phase locked loop (PLL) 51 that provides a frequency and phase signal S_{of} representing the frequency and the phase of the synchronization signal S_{v1} . Specifically, S_{of} represents an instantaneous phase angle of the (sinusoidal) synchronization signal received at the input of the control circuit 5. Thus, signal S_{of} will also be referred to as phase angle signal in the following. The PLL 51 receives the synchronization signal S_{v1} . The frequency and phase signal S_{of} provided by the PLL 51 is received by a signal generator, such as a VCO, that generates a sinusoidal signal S_{i1-REF} being in phase with the synchronization signal S_{v1} and forming a reference signal for the output current i_1 of the converter unit 2.

Referring to FIG. 8, the controller further receives the output current signal S_{i1} and calculates an error signal by subtracting the output current signal S_{i1} from the output current reference signal S_{i1-REF} . The subtraction operation is performed by a subtractor receiving the output current

13

measurement signal S_{i1-REF} and the output current signal S_{i1} at input terminals and providing the error signal at an output terminal. The error signal, which is also a sinusoidal signal is filtered in a filter **53** connected downstream the subtractor **54**. The reference signal S_{REF} is a filtered version of the error signal available at the output of the filter **53**. The filter is, e.g., a proportional (P) filter.

Optionally, a phase signal S_ϕ is added to the output signal of the PLL **51** before generating the sinusoidal reference signal S_{i1-REF} . In this embodiment the reference signal S_{i1-REF} and, therefore, the output current $i1$, has a phase relative to the synchronization signal S_{v1} , with the phase shift being defined by the phase signal S_ϕ .

FIG. 9 illustrates an embodiment of the PLL **51** of FIG. **6**. This PLL includes a phase detector with a calculation unit **511** that calculates the sine or the cosine of the phase angle signal $S_{\omega p}$, and multiplier **512** that receives the output signal from the calculation unit **511** and the synchronization signal S_{v1} . An error signal S_{ERROR} is available at the output of the multiplier **512**. The error signal S_{ERROR} is received by a linear filter (LF) **514**, such as, e.g., a linear proportional-integral (PI) filter. In the steady state, an output signal S_{ω} of the linear filter represents the frequency of the synchronization signal S_{v1} . An integrating circuit (a filter with an integrating (I) characteristic) receives the output signal from the linear filter, integrates the output signal of the linear filter **514** and provides the frequency and phase signal (the phase angle signal) $S_{\omega\phi}$, from which the VCO (see **52** in FIG. **8**) generates the reference signal S_{i1-REF} . Integrating the output signal of the linear filter in the time domain corresponds to a multiplication with $1/s$ in the frequency domain.

FIG. **10** illustrates a further embodiment of the of the controller **5**. In this embodiment, a second PLL **51'** receives the output current signal S_{i1} and calculates a further frequency and phase signal representing frequency and phase of the output current signal S_{i1} . The further frequency and phase signal is subtracted from the frequency and phase signal $S_{\omega\phi}$ representing frequency and phase of the synchronization signal S_{v1} (and, optionally, the phase shift S_ϕ) using a subtractor **54**, so as to provide an error signal. The error signal is filtered using a filter **53** and a signal generator **52**, such as a VCO, receives the error signal and generates a sinusoidal reference signal with frequency and phase defined by the filtered error signal. In this embodiment, the filter **53** can be implemented as a P-filter or as a PI-filter.

FIG. **11** illustrates a further embodiment of one converter unit **2**. This converter unit besides the DC/AC converter **4** and the controller **5** includes a DC/DC converter **6** connected between the input terminals **21**, **22**, and the DC/AC converter **4**. The DC/AC converter **4** may be implemented as explained with reference to FIGS. **6** to **10** with the difference that the DC/AC converter **4** of FIG. **11** receives a DC input voltage $V6$ from the DC/DC converter **6** instead of the input voltage $V3$ of the converter unit **2**. A capacitor **60** connected between the terminals **61**, **62** may represent an output capacitor of the DC/DC converter **6** or an input capacitor **4** of the DC/AC converter **4**, or both. This capacitor **60** can be referred to as DC link capacitor.

The DC/DC converter **6** is configured to adjust the input voltage $V3$ or the input current $I3$ to a voltage or current value, respectively, that is dependent on a reference signal S_{REF-V3} received by the DC/DC converter **6**. For explanation purposes it is assumed that the DC/DC converter **6** adjusts the input voltage $V3$ dependent on the reference signal S_{REF-V3} . Adjusting the input voltage $V3$ of the converter unit **2** may help to operate the DC power source **3** connected to

14

the input terminals **21**, **22**, in an optimum operating point. This will be explained in the following.

A solar cell and, therefore, a PV module including several solar cells, acts like a power generator providing a DC output voltage and a DC output current when it is exposed to sunlight. For a given light power received by the PV array there is a range of output currents and a range of corresponding output voltages at which the PV array can be operated. However, there is only one output current and one corresponding output voltage at which the electric power provided by the PV array has its maximum. The output current and the output voltage at which the output power assumes its maximum define the maximum power point (MPP). The MPP varies dependent on the light power received by the array and dependent on the temperature.

Referring to FIG. **11**, the converter unit **2** further includes a maximum power point tracker (MPPT) **7** that is configured to provide the reference signal S_{REF-V3} such that DC/DC converter **6** adjusts the input voltage such that the DC source **3** is operated in its MPP. The MPPT **7** receives an input current signal S_{i3} that represents the input current $I3$ provided by the DC source **3** (illustrated in dashed lines in FIG. **9**), and an input voltage signal S_{v3} that represents the input voltage $V3$ provided by the DC source **3**. From the input current signal S_{i3} and the input voltage signal S_{v3} the MPPT **7** calculates the instantaneous input power provided by the DC source **3**. The input voltage signal S_{v3} can be obtained from the input voltage $V3$ in a conventional manner by, for example, using a voltage measurement circuit. Equivalently, the input current signal S_{i3} can be obtained from the input current $I3$ in a conventional manner using, for example, a current measurement circuit. Those voltage measurement circuits and current measurement circuits are commonly known and are not illustrated in FIG. **11**.

The basic operating principle of the MPPT **7** in order to find the MPP is to vary the reference signal S_{REF-V3} within a given signal range and to determine the input power provided by the DC source **3** for each of the input voltages $V3$ defined by the different reference signals S_{REF-V3} . The MPPT **7** is further configured to detect the input voltage $V3$ for which the maximum input power has been obtained, and to finally set the reference signal S_{REF-V3} to that value for which the maximum input power has been detected.

Since the solar energy received by the PV array **3** may vary the MPPT **7** is further configured to check whether the DC source **3** is still operated in its maximum power point either regularly or when there is an indication that the maximum power point might have changed. An indication that the maximum power point might have changed is, for example, when the input current $I3$ represented by the input current signal S_{i3} changes without the reference signal S_{REF-V3} having changed. The regular check or the event-driven check of the MPPT **7** whether the DC source **3** is still operated in its maximum power point, may include the same algorithm that has been explained before for detecting the maximum power point for the first time. Conventional algorithms for detecting the maximum power point that can be implemented in the MPPT **7** include, for example, a "hill climbing algorithm" or a "perturb-and-observe algorithm".

The DC/DC converter **6** can be implemented like a conventional DC/DC converter. A first embodiment of a DC/DC converter **6** that can be used in the converter unit **2** is illustrated in FIG. **12**. The DC/DC converter **6** illustrated in FIG. **12** is implemented as a boost converter. This type of converter includes a series circuit with an inductive storage element **64**, such as a choke, and a switch **65** between the input terminals of the DC/DC converter **6**, where the input

15

terminals of the DC/DC converter 6 correspond to the input terminals 21, 22 of the converter unit 2. Further, a rectifier element 66, such as a diode, is connected between a circuit node common to the inductive storage element 64 and the switch 65 and a first output terminal 61 of the DC/DC converter 6. A second output terminal 62 of the DC/DC converter 6 is connected to the second input terminal 22. An output voltage V6 of the DC/DC converter is available between the output terminals 61, 62. Referring to FIG. 12, the DC/DC converter 6 may further include a first capacitive storage element 63, such as a capacitor, between the input terminals 21, 22, and a second capacitive storage element 68, such as a capacitor, between the output terminals 61, 62. The second capacitive storage element 68 acts as an energy storage that is necessary when generating the AC output current i1 from the DC voltage V6 available at the output of the DC/DC converter 6.

The switch 65 can be implemented as a conventional electronic switch, such as a MOSFET or an IGBT. Further, the rectifying element 66 could be implemented as a synchronous rectifier, which is a rectifier implemented using an electronic switch, such as a MOSFET or an IGBT. According to a further embodiment, the switch 65 is implemented as GaN-HEMT.

The DC/DC converter 6 further includes a control circuit (controller) 67 for generating a drive signal S65 for the switch 65. This drive signal S65 is a pulse-width modulated (PWM) drive signal. The PWM controller 67 is configured to adjust the duty cycle of this drive signal S65 such that the input voltage V3 corresponds to the desired input voltage as represented by the reference signal S_{REF-V3} . For this, the control circuit 67 receives the reference signal S_{REF-V3} and the input voltage signal S_{V3} that represents the input voltage V3.

A first embodiment of the PWM control circuit 67 is illustrated in FIG. 13. Like in FIG. 8 (which illustrates an embodiment of the controller 5) in FIG. 11 functional blocks of the controller 67 are illustrated. These functional blocks can be implemented as analog circuits, as digital circuits or can be implemented using hardware and software. Referring to FIG. 13, the control circuit 67 calculates an error signal S_{ERR} from the input voltage signal S_{V3} and the reference signal S_{REF-V3} . The error signal S_{ERR} is calculated by either subtracting the input voltage signal V3 from the reference signal S_{REF-V3} (as illustrated) or by subtracting the reference signal S_{REF-V3} from the input voltage signal S_{V3} . The error signal S_{ERR} is provided by a subtraction element 671 that receives the input voltage signal S_{V3} and the reference signal S_{REF-V3} .

The error signal S_{ERR} is received by a filter 672 that generates a duty cycle signal S_{DC} from the error signal S_{ERR} . The duty cycle signal S_{DC} represents the duty cycle of the drive signal S65 provided by the control circuit 67. The filter 672 can be a conventional filter for generating a duty cycle signal S_{DC} from an error signal S_{ERR} in a PWM controller of a DC/DC converter, such as a P-filter, a PI-filter, or a PID-filter.

A PWM driver 673 receives the duty cycle signal S_{DC} and a clock signal CLK and generates the drive signal S65 as a PWM signal having a switching frequency as defined by the clock signal CLK and a duty cycle as defined by the duty cycle signal S_{DC} . This driver 673 can be a conventional PWM driver that is configured to generate a PWM drive signal based on a clock signal and a duty cycle information. Such drivers are commonly known, so that no further information are required in this regard.

16

The basic control principle of the controller 67 of FIG. 12 will briefly be explained. Assume that the input voltage V3 has been adjusted to a given value represented by the reference signal S_{REF-V3} and that the reference signal S_{REF-V3} changes, so that the input voltage V3 has to be re-adjusted. For explanation purposes it is assumed that the input voltage V3 is to be increased as defined by the reference signal S_{REF-V3} . In this case the control circuit 67 reduces the duty cycle of the drive signal S65. Reducing the duty cycle of the drive signal S65 results in a decreasing (average) input current I3, where decreasing the input current I3, at a given power provided by the DC source 3 results in an increasing input voltage V3. Equivalently, the duty cycle is increased when the input voltage V3 is to be decreased. An increase in the duty cycle results in an increase of the input current I3.

The boost converter according to FIG. 12 does not only provide a load to the DC source 3 in order to operate the DC source 3 in its maximum power point. This boost converter also generates an output voltage V6 received by the DC/AC converter 4 (see FIG. 11) that is higher than the input voltage V3. Further, the boost converter is implemented such that the output voltage V6 is higher than a peak voltage of the output voltage v2 of the DC/AC converter, but lower than a voltage blocking capability of the switches (see 421-424 in FIG. 6) implemented in the DC/AC converter.

Referring to FIG. 14, the DC/DC converter 6 may also be implemented as a buck converter. This buck converter includes a series circuit with an inductive storage element 64, such as a choke, and a switch 65 between the first input terminal 21 and the first output terminal 61. A freewheeling element 66, such as a diode, is connected between the second output terminal 62 and a circuit node common to the inductive storage element 64 and the switch 65. A capacitive storage element 63, such as a capacitor, is connected between the input terminals 21, 22.

Like in the boost converter of FIG. 12, the switch 65 in the buck converter of FIG. 14 can be implemented as a conventional electronic switch, such as a MOSFET or an IGBT, or could be implemented as a GaN-HEMT. Further, the freewheeling element 66 could be implemented as a synchronous rectifier.

Like in the boost converter according to FIG. 12, the switch 65 in the buck converter according to FIG. 14 is driven by a PWM drive signal S65 provided by a control circuit 67. The control circuit 67 may be implemented as illustrated in FIG. 13. The operating principle of the control circuit 67 in the buck converter of FIG. 14 is the same as in the boost converter of FIG. 12, i.e., the duty cycle of the drive signal S65 is increased when the input voltage V3 is to be decreased, and the duty cycle is decreased, when the input voltage V3 is to be increased.

It should be noted that implementing the DC/DC converter 6 as a boost converter (see FIG. 12) or as a buck converter (see FIG. 14) is only an example. The DC/DC converter 6 could also be implemented as a buck-boost converter, a boost-buck-converter, a flyback converter, and so on. Whether a boost converter or a buck converter is used as a DC/DC converter for tracking the maximum power point of the DC source 3 and for providing the input voltage V6 to the DC/AC converter 4, influences the number of converter units 2 to be connected in series in order for the sum of the output voltages v2 of the converter units 2 to correspond to the external AC voltage v1. This will be explained by the way of an example in the following.

Assume that there is an external AC voltage v1 with $240V_{RMS}$ is desired. The peak voltage (maximum amplitude)

17

of this voltage v_1 is $338V$ ($240V \cdot \sqrt{2}$), where $\sqrt{2}$ is the square root). Further assume that the DC sources **3** are PV arrays each providing an output voltage between $24V$ and $28V$ when exposed to sunlight. The DC/AC converter **4** has a buck characteristic, which means that the peak value of the output voltage v_2 (see FIG. **4**) is less than the received DC input voltage V_3 or V_6 , respectively. Thus, when buck converters are employed as DC/DC converters **6** in the converter units **2** or when no DC/DC converters are used, at least 15 converter units **2** with PV panels connected thereto need to be connected in series. This is based on the assumption that each PV array generates a minimum voltage of $V_3=24V$ and that a peak voltage of the external AC voltage v_1 is $338V$. The number of 15 is obtained by simply dividing $338V$ through $24V$ ($338V/24V=14.08$) and rounding the result to the next higher integer.

When, however, a boost converter is used as the DC/DC converter **6** that, for example, generates an output voltage $V_6=60V$ from the input voltage V_3 (which is between $24V$ and $28V$) the number of converter units **2** to be connected in series may be reduced to about 6.

In the DC/AC converter illustrated in FIG. **11**, the output voltage V_6 of the DC/DC converter may vary dependent on the input power received at the input terminals **21, 22** from the DC source **3** and dependent on the output current i_1 or, more exactly, dependent on the average of the output current i_1 . According to a further embodiment illustrated in FIG. **15**, the control circuit **5** is further configured to control the input voltage of the DC/AC converter **4** and the output voltage of the DC/DC converter **6**, respectively. For this, the control circuit **5** receives an input voltage signal SV_6 that represents the input voltage V_6 . The control circuit **5** is configured to adjust the input voltage V_6 by varying the duty cycle of those switches in the DC/AC converter **4** that are driven in a clocked fashion. The input voltage can be increased by generally decreasing the duty cycle and can be decreased by generally increasing the duty cycle. For this, the control circuit **5** includes a further control loop, where this control loop is slower than the control loop that causes the output current i_1 to follow the reference signal S_{REF} . This control loop is, for example configured to cause variations of the duty cycle at a frequency of between 1 Hz and 10 Hz.

The control circuit **5** of FIG. **15** is based on the control circuit illustrated in FIG. **8** and additionally includes a further control loop that serves to adjust the amplitude of the output current reference signal S_{i1-REF} dependent on the input voltage signal S_{V_6} . Instead of the control loop illustrated in FIG. **8**, the control circuit according to FIG. **15** could also be implemented based on the control circuit of FIG. **10**. Referring to FIG. **15**, the control loop includes: a further subtraction element **56**, a filter **55**, and a multiplier **57**. The subtraction element **56** receives the input voltage signal S_{V_6} and a reference signal S_{V_6-REF} that represents a set value of the input voltage V_6 . The subtraction element **56** generates a further error signal based on a difference between the input voltage signal S_{V_6} and the reference signal S_{V_6-REF} . The filter **55** receives the further error signal and generates an amplitude signal S_{AMPL} representing an amplitude of the reference signal S_{REF} from the further error signal. The filter may have a P-characteristic, an I-characteristic, a PI-characteristic, or a PID-characteristic. The amplitude signal S_{AMPL} and the output signal of the VCO **52** are received by the multiplier **57** that provides the output current reference signal S_{i1-REF} . The output current reference signal S_{i1-REF} has an amplitude that is dependent on the input voltage V_6 and that serves to control the input voltage V_6 of the DC/AC converter (**4** in FIG. **11**), and a frequency

18

and phase of the output current i_1 . The frequency and the phase of the reference signal S_{REF} are dependent on the at least one synchronization signal S_{v1} and the output current signal S_{i1} and serve to adjust frequency and phase of the output current i_1 such that there is a given phase difference between the output current and the output voltage.

The input voltage reference signal S_{V_6-REF} may have a fixed value that is, selected such that the input voltage V_6 is sufficiently below the voltage blocking capability of switches employed in the DC/AC converter. However, it is also possible to vary the input voltage reference signal S_{V_6-REF} dependent on the output current, specifically on the rms value of the output current i_1 . According to one embodiment, the input voltage reference signal S_{V_6-REF} decreases when the output current i_1 increases, and the input voltage reference signal S_{V_6-REF} increases when the output current decreases. According to one embodiment, the input voltage reference signal S_{V_6-REF} has a first signal value when the output current i_1 is below a given threshold value, and has a lower second signal value when the output current i_1 is above a given threshold value.

The control circuit illustrated in FIG. **15** could also be implemented in a converter as illustrated in FIG. **6** in which the DC/DC converter is omitted. In this case, the input voltage to be controlled is the output voltage V_3 of the PV module, so that the voltage signal S_{V_6} in FIG. **15** is replaced by the voltage signal S_{V_3} representing the output voltage of the DC source **3**, and the input voltage reference signal S_{V_6-REF} is replaced by the reference signal S_{V_3-REF} defining a desired output voltage of the DC source **3**. The input voltage reference signal S_{V_3-REF} may in this case be provided by an MPPT in order to operate the DC source (PV module) **3** in its MPP.

FIG. **16** illustrates a further embodiment of DC/DC converter **6** that can be implemented in a DC/AC converter unit **2** of FIG. **11**. The DC/DC converter of FIG. **16** is implemented as a boost converter with two converter stages **60₁**, **60₂**. The two converter stages **60₁**, **60₂** are connected in parallel between the input terminals **21**, **22** and the output terminals **61**, **62**. Each of the converter units **60₁**, **60₂** is implemented like the boost converter of FIG. **12** and includes a series circuit with an inductive storage element **64₁**, **64₂**, such as a choke, and a switch **65₁**, **65₂** between the input terminals of the DC/DC converter **6**, where the input terminals of the DC/DC converter **6** correspond to the input terminals **21**, **22** of the converter unit **2**. Further, each converter stage includes a rectifier element **66₁**, **66₂** such as a diode, connected between a circuit node common to the corresponding inductive storage element **64₁**, **64₂** and the corresponding switch **65₁**, **65₂** and the first output terminal **61** of the DC/DC converter **6**. The second output terminal **62** of the DC/DC converter **6** is connected to the second input terminal **22**.

The two converter stages **60₁**, **60₂** share the first capacitive storage element **63** between the input terminals **21**, **22**, and share the second capacitive storage element **68** between the output terminals **61**, **62**. The output voltage V_6 of the DC/DC converter **6** is available across the second capacitive storage element **68**.

Referring to FIG. **16**, the control circuit (controller) **67** of the DC/DC converter **6** generates two PWM drive signals S_{65_1} , S_{65_2} , namely a first drive signal S_{65_1} for the switch **65₁** of the first converter stage **60₁**, and a second drive signal S_{65_2} for the switch **65₂** of the second converter stage **60₂**. According to one embodiment, the first and second boost converter stages **60₁**, **60₂** are operated interleaved, which means that there is a time offset between the switching

19

cycles of the first switch **65**₁ and the switching cycles of the second switch **65**₂. Providing two converter stages **60**₁, **60**₂ and operating these converter stages **60**₁, **60**₂ in an interleaved mode helps to reduce voltage ripples of the input voltage **V3** and the output voltage **V6** of the DC/DC converter **6**. Of course, more than two boost converter stages **60**₁, **60**₂ can be connected in parallel.

Referring to FIG. **16**, each boost converter stage **60**₁, **60**₂ provides an output current **I6**₁, **I6**₂. These output currents **I6**₁, **I6**₂ add and form the overall output current **I6** of the DC/DC converter. FIG. **17** illustrates a first embodiment of the controller **67** configured to generate PWM drive signals **S65**₁, **S65**₂ for each converter stage **60**₁, **60**₂, and further configured to generate the PWM drive signals **S65**₁, **S65**₂ such that the output currents **I6**₁, **I6**₂ of the converter stages **60**₁, **60**₂ are balanced.

Referring to FIG. **17** the control circuit **67** is based on the control circuit **67** of FIG. **13** and includes the subtraction element **671** receiving the input voltage signal **S_{V3}** and the input voltage reference signal **S_{REF-V3}** and the filter **672** for providing the duty cycle signal **S_{DC}**. The controller **67** of FIG. **17** further includes a first PWM driver **673**₁ receiving a first duty cycle signal **S_{DC1}** that is dependent on the duty cycle signal **S_{DC}** provided by the filter **672** and receiving a first clock signal **CLK**₁, and a second PWM driver **673**₂ receiving a second duty-cycle signal **S_{DC2}** that is dependent on the duty cycle signal **S_{DC}** provided by the filter **672** and receiving a second clock signal **CLK**₂. According to one embodiment, the first and second clock signals **CLK**₁, **CLK**₂ have the same frequency. However, there is a phase shift between the first and second clock signal **CLK**₁, **CLK**₂, so that there is a phase shift between the first PWM drive signal **S65**₁ provided by the first PWM driver **673**₁ and the second PWM drive signal **S65**₂ provided by the second PWM driver **673**₂.

If the first and second converter stages **60**₁, **60**₂ would perfectly match so that there would be no risk of unbalanced output currents **I6**₁, **I6**₂, the duty cycle signal **S_{DC}** could be used as the first duty cycle signal **S_{DC1}** and as the second duty cycle signal **S_{DC2}**. However, due to an inevitable mismatch of the components in the converter stages **60**₁, **60**₂ the output currents **I6**₁, **I6**₂ can be unbalanced when the first and second drive signal **S65**₁, **S65**₂ would be generated with exactly the same duty cycle.

In order to compensate for such unbalances of the first and second output currents **I6**₁, **I6**₂, the controller **67** of FIG. **17** includes an additional control loop, that can be referred to as current balancing loop or power balancing loop. This control loop receives a first output current signal **S_{I61}** representing the first output current **I6**₁ of the first converter stage **60**₁, and a second output current signal **S_{I62}** representing the output current **I6**₂ of the second converter stage **60**₂. These output current signals **S_{I61}**, **S_{I62}** can be generated using conventional current measurement units. The output current signals **S_{I61}**, **S_{I62}** are received by a subtraction unit **675** that generates a further error signal **S_{ERR2}**. The further error signal **S_{ERR2}** is representative of a difference between the first and second output currents **I6**₁, **I6**₂. Further error signal **S_{ERR2}** is received by a filter **676** that generates a filtered error signal. The filter **676** may have a P-characteristic, a I-characteristic, or a PI-characteristic.

A further subtraction unit **674**₁ subtracts the filtered error signal from the duty cycle signal **S_{DC}** to generate the first duty cycle signal **S_{DC1}**, and an adder **674**₂ adds the filtered error signal to the duty cycle signal **S_{DC}** to generate the second duty cycle signal **S_{DC2}**.

20

The operating principle of the controller **67** of FIG. **17** is as follows. When the first and second output currents **I6**₁, **I6**₂ are identical, the further error signal **S_{ERR2}** is zero. In this case, the first duty cycle signal **S_{DC1}** corresponds to the second duty cycle signal **S_{DC2}**. When, for example, the first output current **I6**₁ is larger than the second output current **I6**₂, the further error **S_{ERR2}** and the filtered error signal have a positive value. In this case, the duty cycle signal **S_{DC1}** (obtained by subtracting the filtered error signal from the duty cycle signal **S_{DC}**) becomes smaller than the second duty cycle signal **S_{DC2}** (obtained by adding the filtered error signal to the duty cycle signal **S_{DC}**). Thus, the duty cycle of the first drive signal **S65**₁ becomes smaller than the duty cycle of the second drive signal **S65**₂ in order to reduce the first output current **I6**₁ and to increase the second output current **I6**₂, so as to balance these output currents **I6**₁, **I6**₂.

FIG. **18** illustrates a further embodiment of the control circuit **67** that is configured to balance the output currents **I6**₁, **I6**₂. The control circuit **67** of FIG. **18** is based on the control circuit **67** of FIG. **17**. In the control circuit **67** of FIG. **18**, the subtraction unit **674**₁ that generates the first duty cycle signal **S_{DC1}** does not receive the duty cycle signal **S_{DC}** but receives a filtered version of a difference between the duty cycle signal **S_{DC}** and the first output current signal **S_{I61}**. A subtraction unit **677**₁ calculates the difference and a filter **678**₁ filters the difference. The filter may have a P-characteristic, an I-characteristic or PI-characteristic. Equivalently, the adder **674**₂ that provides the second duty cycle signal **S_{DC2}** does not receive the duty cycle signal **S_{DC}** but receives a filtered difference between the duty cycle signal **S_{DC}** and the second input current signal **S_{I62}**. A subtraction unit **677**₂ calculates the difference between the duty cycle signal **S_{DC}** and the second output current signal **S_{I62}**, and a filter **678**₂ filters the difference. The output signals of the filter **678**₁, **678**₂ are received by the subtraction unit **674**₁ and the adder **674**₂, respectively.

While in the embodiment illustrated in FIG. **17** a single control loop is employed to regulate the input voltage **V3**, a dual control loop structure is employed in the embodiment according to FIG. **18**.

FIG. **19** illustrates a further embodiment of a converter unit **2** with a DC/AC converter **4**. The converter unit **2** may further include a DC/DC converter **6** (see FIG. **9**) connected between the input terminals **21**, **22** and the DC/AC converter. However, such DC/DC converter is not illustrated in FIG. **13**. Dependent on whether or not the converter unit **2** includes a DC/DC converter the DC/AC converter **4** receives the input voltage **V3** of the converter unit **2** or the output voltage of the DC/DC converter **4** (not illustrated in FIG. **19**) as an input voltage. Just for explanation purposes it is assumed that the DC/AC converter **4** receives the input voltage **V3**.

The DC/AC converter of FIG. **19** includes a buck converter **80** that receives the input voltage **V3** as an input voltage. The buck converter **80** is configured to generate an output current **i80** which is a rectified version of the output current **i1** of the DC/AC converter **4**. Assume, for example that a desired waveform of the output current **i1** is a sinusoidal waveform. In this case, the output current **i80** provided by the converter **80** has the waveform of a rectified sinusoidal curve or the waveform of the absolute value of a sinusoidal curve, respectively. This is schematically illustrated in FIG. **20**, in which exemplary timing diagrams of a sinusoidal output current **i1** and the corresponding output current **i80** of the converter **80** are illustrated.

The output current **i1** of the DC/AC converter **4** is produced from the output current **i80** of the buck converter

21

80 using a bridge circuit 85 with two half-bridges, where each of these half-bridges is connected between output terminals 81, 82 of the buck converter 80. This bridge circuit 85 can be referred to as unfolding bridge. A first half-bridge includes a first and a second switch 85₁, 85₂ connected in series between the output terminals 81, 82, and a second half-bridge includes a third switch 85₃ and a fourth switch 85₄ connected in series between the output terminals 81, 82. An output terminal of the first half-bridge, which is a circuit node common to the first and second switches 85₁, 85₂ is coupled to the first output terminal 23. An output terminal of the second half-bridge, which is a circuit node common to the third and fourth switch 85₃, 85₄ is coupled to the second output terminal 24 of the converter unit 2. Optionally, an EMI filter 88 with two inductances, such as chokes, is coupled between the output terminals of the half-bridges and the output terminals 23, 24 of the converter unit 2. The output capacitance C of the converter unit 2 that is connected between the output terminals can be part of the EMI filter 88.

Referring to FIG. 19, the output current i₈₀ of the buck converter 80 has a frequency which is twice the frequency of the output current i₁. A switching frequency of the switches 85₁-85₄ of the bridge circuit 85 corresponds to the frequency of the output current i₁. During a positive half-cycle of the output current i₁ the first and fourth switch 85₁, 85₄ are switched on, and during a negative half-cycle of the output voltage v₂ the second and third switches 85₂, 85₃ are switched on. The switches of the bridge circuit 85 are driven by drive signals S85₁-S85₄ generated by a drive circuit 88. Timing diagrams of these drive signals S85₁-S85₄ are also illustrated in FIG. 20. In FIG. 20, a high signal level of these timing diagrams represents an on-level of the corresponding drive signal S85₁-S85₄. An on-level of the drive signal is a signal level at which the corresponding switch is switched on. The drive signals S85₁-S85₄ may, for example, be generated dependent on the output voltage v₈₀ of the buck converter 80, where, according to one embodiment, drive circuit 88 changes the switching state of the switches each time the output voltage v₈₀ has decreased to 0. "Changing the switching state" means either switching the first and the fourth switches 85₁, 85₄ on and the other two switches off, or means switching the second and the third switch 85₂, 85₃ on and the other two switches off.

The buck converter 8 may have a conventional buck converter topology and may include a switch 83 connected in series with an inductive storage element 84, where the series circuit is connected between the first input terminal 21 of the converter unit 2 or the first output terminal 61 of a DC/DC converter (not shown), and the first output terminal 81 of the buck converter 80, respectively. A rectifier element 86 is connected between the second output terminal 82 (corresponding to the second input terminal 22) of the buck converter and a circuit node common to the switch 83 and the inductive storage element 84. The switch 83 can be implemented as a conventional electronic switch, such as a MOSFET or an IGBT, or as a GaN-HEMT. The rectifier element 86 can be implemented as a diode or as a synchronous rectifier. Further, a capacitive storage element 85, such as a capacitor, is connected between the input terminals of the buck converter 80, and an optional smoothing capacitor 89 is connected between the output terminals 81, 82.

The switch 83 of the buck converter 80 is driven by a PWM drive signal S83 generated by a control circuit or controller 87. The controller 87 of the buck converter 80 receives the reference signal S_{REF} from the controller 5 of the converter unit 2. The controller 87 of the buck converter 80 is configured to generate its output current i₈₀ in corre-

22

spondence with the reference signal S_{REF}. This reference signal S_{REF} according to FIG. 19, unlike the reference signal S_{REF} of FIG. 11, does not have the waveform of the output current i₁, but has the waveform of the rectified output current i₁. This reference signal S_{REF} is also generated from the synchronization signal S_{v1} and the output current signal S_{i1}.

The controller 5 for generating the reference signal S_{REF} according to FIG. 19 may correspond to the controllers illustrated in FIGS. 8 and 15 with the difference that the oscillating signal provided at the output of the oscillator 53 is rectified. An embodiment of the controller 5 according to FIG. 19 is illustrated in FIG. 21. This controller 5 corresponds to the controller according to FIG. 8 with the difference that the output signal of the filter 53 is received by a rectifier 58 that generates a rectified version of the oscillating output signal of the oscillator 53. Mathematically this is equivalent to forming the absolute value of the oscillating output signal of the oscillator 53. The reference signal S_{REF} is available at the output of the rectifier 58.

FIG. 22 illustrates a further embodiment of a controller 5 that can implemented in the DC/AC converter 4 of FIG. 19. The controller 5 of FIG. 22 is based on the controller 5 of FIG. 15 with the difference that the amplitude signal S_{AMPL} is generated from the input voltage signal S_{V3} voltage signal S_{V3} that represents the input voltage V3 provided by the DC source 3, and from the input voltage reference signal S_{REF-V3}. The input voltage reference signal S_{REF-V3} can be generated by an MPPT, such as an MPPT 7 explained with reference to FIG. 11.

The control loops illustrated in FIGS. 15, 21 and 22 could, of course, be amended to be based on the control loop structure of FIG. 10 instead of FIG. 8.

Referring to FIG. 19, the controller 87 of the buck converters 80 can be implemented like a conventional controller for providing a PWM drive signal in a buck converter. The controller 86 receives the reference signal S_{REF} and an output current signal S_{i80}, where the output current signal S_{i80} represents the output current v₈₀ of the buck converter 80. The controller 86 is configured to vary the duty cycle of the drive signal S83 such that the output current i₈₀ of the buck converter 80 is in correspondence with the reference signal S_{REF}. The functionality of this controller 86 corresponds to the functionality of the controller 67 illustrated in FIG. 13. In the embodiment illustrated in FIG. 19 the controller receives the output current signal S_{i1} representing the output current i₁ and the synchronization signal S_{v1} for generating the reference signal S_{REF}. However, this is only an example. It would also be possible to generate the reference signal S_{REF} based on signals representing the output voltage v₈₀ and the output current i₈₀ of the buck converter 80. In this case, the reference signal is generated such that output current i₈₀ and the output voltage v₈₀ of the buck converter 80 have a given phase difference.

The operating principle of a power converter circuit 1 including DC/AC converters as illustrated in FIG. 19 will now be explained with reference to FIGS. 1 and 19. The explanation will be based on the assumption that the voltage of the power grid 100 is a sinusoidal voltage so that an output current i₁ with a sinusoidal waveform is desired. Further, it is assumed that the input powers of the individual DC/AC converters is zero, while the power grid voltage v_N is applied to the input terminals 11, 12 and the bridge circuits 85 in the individual converter units are in operation. In this case, the smoothing capacitors 89 of the buck converters are connected in series between the output terminals 11, 12.

23

When the individual capacitors **89** have the same size, the voltage across each of these capacitors **89** is $1/n$ times the power grid voltage v_N .

Assume now that the DC/AC converters receives an input power from the PV modules **3** connected thereto. The DC/AC converters then adjust their common output current $i1$ to be in phase with the external voltage $v1$ (the power grid voltage). The amplitude of the output current $i1$ is, in particular, controlled through the input voltage $V3$, where the current is increased when the voltage $V3$ increases, and the current is decreased when the voltage $V3$ decreases.

When the output current $i1$ provided by one DC/AC converter decreases, a current that corresponds to a difference between the output current $i1$ and the common current $i1_{OUT}$ is provided by the output capacitor C which causes the voltage $v2$ across the output capacitor C to decrease until the input power provided to the DC/AC converter corresponds to its output power. A decrease of the voltage $v2$ across the output capacitor **89** of one DC/AC converter **4** or one converter unit **2** causes an increase of the voltages across the output capacitors of the other converter units. This process proceeds until the converter unit **2** has settled in stable operation point at a lower output current $i1$. If the other converter units **2** at first continue to run at the same duty cycle, the increase of the voltages across their output capacitors leads to a reduction of their output currents $i1$ (and hence to a reduction of the common output current) in order to keep their output powers equal their input powers. When the output current $i1$ provided by one DC/AC converter increases so as to be higher than the common current $i1_{OUT}$, the corresponding output capacitor C is charged which results in an increase of the voltage across the output capacitor C of the one converter and a decrease of the voltage across the output capacitors of the other converters.

It became obvious from the explanation provided before that besides the control loops in the individual converter units **2** no additional control loop is required in order to control the output voltages of the individual converter units **2**. The power converter circuit **1** with the converter units **2** is "self organizing". Referring to FIG. 1, assume that, for example, in the steady state the input power provided by the first DC source **3**₁ to the first converter unit **2**₁ would drop, for example because the corresponding PV array is shaded. The output voltage $v2_1$ of the corresponding converter unit **2** would then drop, while the output voltages of the other converter units **2**₂, **2**_{*n*} would increase in order to meet the condition defined by equation (1). Further, the common output current $i1_{OUT}$ would decrease. The transient process is as follows: When the input power received by the first converter unit **2**₁ decreases, the common output current $i1_{OUT}$ at first remains unchanged, while the output current $i1_1$ of the first converter unit **2**₁ decreases. The decrease of the output current $i1_1$ and the unchanged common output current $i1_{OUT}$ causes a discharging of the output capacitor C_1 of the first converter unit **2**₁ so that the output voltage $v2_1$ decreases. A decrease of the output voltage of the first converter unit, however, causes an increase of the output voltages of the other converters, which now decrease their output currents in order to keep their output powers equal their input powers. The transition processes finishes when a "new" common output current $i1_{OUT}$ has settled in to which the individual output currents $i1$ correspond. This is a self-organizing and self-stabilizing process that does not require and additional control loop besides the control loops in the individual converter units **2** disclosed before.

FIG. 23 illustrates a further embodiment of a power converter circuit. In this power converter circuit two series

24

circuits **1**_{*P*}, **1**_{*H*} each including one group with a plurality of converter units **2**_{*H*}-**2**_{*m*} and **2**_{*HH*}-**2**_{*mn*} connected in series are connected in parallel between the output terminals **11**, **12**. Each of the series circuits **1**_{*P*}, **1**_{*H*} can be implemented in accordance with the series circuit **1** of converter units **2**₁-**2**_{*n*} explained before. The converter units of the two groups (the two series circuits) are coupled to the same synchronization circuit **10** that can be implemented in accordance with one of the embodiments explained before. Of course, more than two series circuits each with a plurality of converter units can be connected in parallel.

Referring to the explanation herein before, the synchronization circuit **10** can be implemented as a voltage measurement circuit that measures the external AC voltage $v1$ and that generates the at least one synchronization signal S_{v1} such that the synchronization signal is a continuous signal representing the external AC voltage $v1$ and, therefore, having the same frequency and phase as the external AC voltage $v1$. FIG. 24 illustrates a further embodiment of the synchronization circuit **10**.

In the embodiment illustrated in FIG. 24, the synchronization circuit **10** receives the external AC voltage $v1$ available at the output terminals **11**, **12** and generates the synchronization signal S_{v1} as a continuous signal with a frequency and a phase that is dependent on the frequency and the phase of the external AC voltage $v1$, respectively. According to one embodiment, the synchronization circuit **10** receives a phase-shift signal SPS that defines a desired phase shift between the synchronization signal S_{v1} and the external AC voltage $v1$. In the embodiment illustrated in FIG. 24, the synchronization circuit **10** includes a phase-shift circuit **110** that provides an output voltage $v1'$. The output voltage $v1'$ of the phase-shift circuit **110** has a phase shift relative to the external AC voltage $v1$, with the phase shift being defined by the phase-shift signal S_{PS} . A transmission circuit **120** receives the output voltage $v1'$ of the phase-shift circuit **110** and generates the at least one synchronization signal S_{v1} transmitted to the individual converter units **2** (not illustrated in FIG. 24).

Referring to FIG. 25, the transmission circuit **120** may be implemented as a voltage divider having a plurality of voltage divider elements **120**₁, **120**₂, **120**_{*n*} connected in series. The voltage divider of the transmission circuit **120** is similar to the voltage divider illustrated in FIG. 3. The individual voltage divider elements **120**₁-**120**_{*n*} of the voltage divider **120** can be implemented like the voltage divider elements **10**, explained with reference to FIGS. 4A to 4C and 5. Referring to FIG. 25, each of the voltage divider elements **120**₁-**120**_{*n*} provides a voltage $v1_1$, $v1_2$, $v1_n$, with each of these voltages representing one synchronization signal received by one converter unit **2** (not illustrated in FIG. 25) in the same way as the individual converter units **2**₁-**2**_{*n*} of FIG. 3 receive the individual voltages $v1_1$, $v1_2$, $v1_n$.

When employing a synchronization circuit **10** as illustrated in FIG. 24, a phase shift between the output currents $i1$ of the individual converter units **2** and the external AC voltage $v1$ can be adjusted through the phase-shift signal S_{PS} , so that there is no need to individually provide phase shift signals (S_ϕ in FIGS. 15, 21 and 22) to the individual converter units **2**. However, it is of course possible to additionally provide phase shift signals to the individual converter units **2**.

Transmitting the at least one synchronization signal S_{v1} to the individual converter units through a voltage divider, as illustrated in FIG. 25, is only one possible embodiment. According to further embodiments, the at least one synchronization signal S_{v1} is transmitted to the individual converter

25

units **2** via a signal bus, a radio path, or via a power line using power line communication. Of course, corresponding receiver circuits are employed in the converter units **2** in this case.

Referring to power line communication, standard power line communication circuits can be used for the communication between the synchronization circuit **10** and the individual converter units **2** since the output current Because i_{OUT} of the converter circuit is an AC current. In this case, the power line of the converter circuit **1**, which is the line carrying the output current i_{OUT} and connecting the outputs of the individual converter units **2** is used for the communication. A first power line communication interface (not shown) coupled to the power line receives the synchronization signal S_{v1} and forwards the synchronization signal S_{v1} suitably modulated via the power line to the individual converter units **2**. Each converter unit includes a corresponding power line communication interface coupled to the power line and configured to receive and demodulate the modulated synchronization signal S_{v1} .

According to a further embodiment, that is illustrated in dashed lines in FIG. **24**, the synchronization circuit does not only receive a phase-shift signal S_{PS} but additionally to the phase shift signal S_{PS} or instead of the phase shift signal S_{PS} receives a control signal S_{CTRL} through which other parameters of the synchronization signal S_{v1} , such as the frequency and/or the amplitude of the synchronization signal S_{v1} can be adjusted. In this embodiment, the synchronization signal S_{v1} can be generated independent of the external AC voltage v_1 , which may be helpful in some operation scenarios explained below.

Referring to the explanation herein before, the synchronization signal S_{v1} received by each converter unit **2** can be a continuous signal that is continuously transmitted from the synchronization circuit **10** to the converter units **2**. Each of the converter units **2** continuously generates its corresponding output current i_1 in accordance with the synchronization signal S_{v1} , which means with a frequency and a phase defined by the synchronization signal S_{v1} .

According to a further embodiment, the synchronization signal S_{v1} is a pulse signal including a sequence of signal pulses and the individual converter **2** units are configured to generate a continuous signal having a frequency and a phase from the pulse signal.

FIG. **26** illustrates an embodiment of a converter unit **2** that is configured to receive a pulse signal as a synchronization signal S_{v1} . The converter unit of FIG. **26** corresponds to the converter units of FIGS. **5** and **11** and additionally includes a signal generator **20** that receives the pulsed synchronization signal S_{v1} and that is configured to generate a continuous sinusoidal synchronization signal S_{v1} from the pulsed signal S_{v1} . In this embodiment, the continuous synchronization signal S_{v1} provided at the output of the signal generator **20** is received by the control circuit **5** and is processed in the control circuit **5** in the same way as a continuous sinusoidal synchronization signal S_{v1} explained herein before.

According to one embodiment, the pulsed synchronization signal S_{v1} is a periodic signal having signal pulses that are equally distant, and signal generator **20** is configured to generate a sinusoidal signal S_{v1} from the pulsed signal S_{v1} . According to one embodiment, the signal generator **20** generates the sinusoidal synchronization signal S_{v1} such that a zero crossing of the sinusoidal signal S_{v1} occurs each time a signal pulse of the pulsed synchronization signal S_{v1} occurs. In this embodiment, the mutual distance of the signal pulses defines the frequency of the continuous synchroni-

26

zation signal S_{v1} generated by the signal generator **20** and the absolute position of the individual signal pulses on the time scale defines the phase of the continuous synchronization signal. An embodiment of a signal generator **20** configured to receive a pulsed synchronization signal S_{v1} and configured to generate a continuous sinusoidal synchronization signal S_{v1} with a frequency and a phase as defined by the pulsed synchronization signal S_{v1} is illustrated in FIG. **27**. Timing diagrams of signals occurring in this signal generator are illustrated in FIG. **28**.

Referring to FIG. **27**, the signal generator includes an integrator **202** receiving the pulsed synchronization signal S_{v1} as a clock signal. A timing diagram of an embodiment of the pulsed synchronization signal S_{v1} is illustrated in FIG. **28**. The integrator is configured to integrate a constant signal C received at a second input beginning with each signal pulse of the pulsed synchronization signal S_{v1} . An output signal of the integrator **202** is a ramp signal S_{RAMP} with a frequency corresponding to the frequency of the pulsed synchronization signal S_{v1} . The constant signal is provided by a calculation unit **201** that receives pulsed signal S_{v1} and calculates the constant signal C to be proportional to the frequency of the pulsed synchronization signal S_{v1} , or to be inversely proportional to a time period T (see FIG. **28**) of the pulsed signal S_{v1} . In the steady state, the slope of the individual ramps of the ramp signal S_{RAMP} is dependent on the frequency (and decreases when the frequency is reduced) and the amplitudes of the individual ramps are equal. According to one embodiment, the calculation unit **201** calculates the constant value C in each cycle of the pulsed signal S_{v1} and provides the calculated value to the integrator in the next cycle. Thus, a frequency change of the synchronization becomes effective in the generation of the ramp signal S_{RAMP} with a delay of one cycle of the pulsed signal.

Referring to FIG. **27**, a trigonometric function generator **203** receives the ramp signal S_{RAMP} and generates the continuous synchronization signal S_{v1} by calculating the sine or the cosine of instantaneous values of the ramp signal S_{RAMP} . The resulting continuous synchronization signal S_{v1} is illustrated in FIG. **28**. In the embodiment illustrated in FIGS. **27** and **28** the continuous synchronization signal S_{v1} has a zero crossing from negative to positive signal values each time a signal pulse of the pulsed synchronization signal occurs.

Of course, the signal generator of FIG. **27** could easily be modified to generate the continuous synchronization signal S_{v1} such that with each pulse of the pulsed signal S_{v1} a zero crossing from positive to negative signal values occurs.

According to one embodiment, the pulsed synchronization signal S_{v1} is only transmitted for a short time when a frequency and/or phase of the pulsed signal changes. This means, only a short sequence with some cycles of the pulsed signal S_{v1} is transmitted, while after the transmission of the sequence the pulsed signal is interrupted for a time period significantly longer than one cycle period. This interruption may be several seconds or several minutes. In this embodiment, a clock generator receives the pulsed signal S_{v1} . The clock generator is configured to measure the frequency of the pulsed signal S_{v1} and to generate a clock signal provided to the integrator with a frequency corresponding to the measured frequency of the pulsed signal S_{v1} . The clock generator is, in particular configured to store the frequency information and to generate the clock signal even in those time periods when the pulsed signal S_{v1} has been switched off and updates the frequency each time a new sequence of the pulsed signal S_{v1} is transmitted. Equivalently, the calculation unit stores the calculated value C until a new

sequence of the pulsed signal S_{v1} is transmitted that allows the calculation unit **201** to re-calculate the constant value.

According to a further embodiment, the synchronization signal S_{v1} is an AC signal that is only transmitted for a certain time period, such as, for example, for a duration corresponding to only several periods of the AC signal. In this embodiment, the signal generator **20** is configured to evaluate a frequency and a phase information of the synchronization signal S_{v1} and is configured to generate the continuous synchronization signal S_{v1} based on this frequency and time information. In this embodiment, the synchronization signal S_{v1} may be transmitted only once at the beginning of the operation of the power converter circuit **1** to the individual converter units, or may be transmitted periodically during the operation of the power converter circuit **1**.

An embodiment of a signal generator **20** that is configured to generate a continuous (sinusoidal) synchronization signal S_{v1} from a synchronization signal S_{v1} that is available for only several periods is illustrated in FIG. **29**. The signal generator of FIG. **29** is based on the signal generator of FIG. **27** and additionally includes a zero crossing detector **205** receiving the synchronization signal S_{v1} and configured to generate a pulse signal. The pulse signal generated by the zero crossing detector includes a signal pulse each time a positive or a negative zero crossing is detected. The pulse signal provided by the zero crossing detector **205** is then processed by the clock generator **204**, the calculation unit **201**, the integrator **202**, and the trigonometric function generator **203** as explained with reference to FIGS. **27** and **28**. In this embodiment, the continuous synchronization signal S_{v1} is synchronized to the synchronization signal S_{v1} during that time period when the synchronization signal S_{v1} is available and, after the synchronization signal has been switched off, continues to generate the continuous synchronization signal S_{v1} based on the frequency and phase information stored in the clock generator **204** and the calculation unit **201**.

According to a further embodiment, the synchronization signal S_{v1} transmitted to the individual converter units corresponds to the frequency and phase signal $S_{\omega t}$ explained with reference to FIGS. **15**, **21** and **22**. In this embodiment, the signal generator **20** can be omitted and the control circuit **5** can be simplified by omitting the PLL **51**.

In each of the individual cases where different signal waveforms of the synchronization signal S_{v1} have been discussed, the synchronization signal S_{v1} can be generated by the synchronization circuit **10** connected between output terminals **11**, **12**.

So far, the operation of the power converter circuit in a normal operation mode has been explained. In the normal operation mode, each of the individual converter units **2** is configured to generate its output current $i1$ such that the output current $i1$ has a frequency and the phase as defined by the synchronization signal S_{v1} received by the converter unit **2**. Besides the normal operation mode other operation modes of the power converter circuit **1** as well.

According to one embodiment, that is schematically illustrated in FIG. **30**, the power converter circuit **1** is either operated in the normal mode **901** or in a standby mode **902**. In the standby mode **902** the individual converter units **2** are deactivated so that the output currents $i1$ of the individual converter units **2** are zero, but may again be activated.

For example, the power converter is, e.g. in the standby mode, when the supply voltages ($V3_1$ - $V3_n$ in FIG. **1**) provided by the DC power sources are too low for generating

the output currents $i1$. When the individual DC power sources 3_1 - 3_n are implemented as PV modules, this may occur at night.

The power converter circuit **1** switches from the normal mode **901** to the standby mode **902** when a shut-down condition is met, and changes from the standby mode **902** to the normal mode when a start-up condition is met. The process of switching the power converter circuit **1** from the normal mode to the standby mode will be referred to as shut down and a sequence of operations involved in this process will be referred to as shut-down sequence in the following. The process of switching the power converter circuit **1** from the standby mode to the normal mode will be referred to as start-up and a sequence of operations involved in this process will be referred to as start-up sequence in the following.

The power converter circuit **1** may include an operation mode controller that defines the operation mode of the power converter circuit **1**. With other words, the operation mode controller **50** controls the overall operation of the power converter circuit **1**. FIG. **31** illustrates a block diagram of a power converter circuit **1** that includes an operation mode controller **50**. The operation mode controller **50** can be implemented as a microprocessor, an ASIC, a digital signal processor, a state machine, or the like.

In the embodiment illustrated in FIG. **31**, the operation mode controller **50** receives at least one operation parameter of the power converter circuit **1** from a measurement unit **60**, is configured to control a connection circuit **70** connected between the series circuit with the individual converter units 2_1 - 2_n and the output terminals **11**, **12**, and is configured to control the synchronization unit **10**. The measurement circuit **60** is configured to measure at least one of the output current i_{OUT} of the series circuit with the converter units 2_1 - 2_n , and a voltage v_{OUT} across the series circuit 2_1 - 2_n . As schematically illustrated in FIG. **31**, the measurement circuit **60** may include a current measurement circuit **60** for measuring the output current i_{OUT} , and a voltage measurement circuit **602** for measuring the output voltage v_{OUT} . The output voltage v_{OUT} across the series circuit corresponds to the external AC voltage v_1 when the series circuit is connected to the output terminals **11**, **12**. The connection circuit **70** that is configured to either connect the series circuit 2_1 - 2_n to the output terminals **11**, **12** or to disconnect the series circuit 2_1 - 2_n from the output terminals **11**, **12** may include two switches, namely a first switch **701** connected between the series circuit 2_1 - 2_n and the first output terminal **11** and a second switch **702** connected between the series circuit 2_1 - 2_n and the second output terminal **12**. These switches **701**, **702** can be implemented as conventional switches, such as relays or semiconductor switches (MOSFETs, IGBTs, etc.). Referring to FIG. **31**, the connection circuit **70** may include an optional third switch **703** connected in parallel with the series circuit 2_1 - 2_n . This switch **703** may be closed when an output voltage of the series circuit with the individual converter units **2** is above a given voltage threshold, in order to limit the output voltage. Optionally, a resistor or another type of current limiting element is connected in series with this switch **703**.

In FIG. **31**, signal $S60$ provided by the measurement circuit **60** to the operation mode controller **50** represents the at least one operation parameter measured by the measurement circuit **60**. This measurement signal $S60$ includes information on at least one of the output current i_{OUT} and the output voltage v_{OUT} . Signal $S70$ in FIG. **31** schematically illustrates a control signal generated by the operation mode controller **50** and received by the connection circuit **70**.

29

Dependent on the control signal S_{70} , the connection circuit 70 connects the series circuit to the output terminals 11, 12, disconnects the series circuit from the output terminals 11, 12, or short-circuits the series circuit 2₁-2_n.

Referring to FIG. 31, the operation mode controller 50 further controls the synchronization circuit 10 that generates the synchronization signal S_{v1} . In FIG. 31, only the control signal S_{CTRL} is drawn to be received by the synchronization circuit 10. The control signal S_{CTRL} defines the signal parameters of the synchronization signal S_{v1} , such as frequency, phase and amplitude. As controlled by the control signal S_{CTRL} the synchronization signal S_{v1} can be dependent on the external AC voltage v_1 also received by the synchronization circuit 10, such as have a given phase shift (zero or other than zero) relative to the external AC voltage, or the synchronization signal S_{v1} can be independent of the external AC voltage v_1 . Referring to the explanation below, there may be operating scenarios (such as fault ride through) where it is necessary to generate the synchronization signal S_{v1} independent of the external AC voltage v_1 .

In the power converter circuit of FIG. 31, the synchronization signal S_{v1} is not only used in the normal mode to provide a synchronization information to the individual converter units 2 for generating the output currents $i1$, but is also used in the standby mode for signalling the individual converter units 2 that a change from the standby mode to the normal mode is desired. In this power converter circuit 1, the operation mode controller 50 has the synchronization circuit 10 generate the synchronization signal S_{v1} with a standby waveform in the standby mode. The standby waveform is a waveform that is different from the signal waveform of the synchronization signal S_{v1} in the normal mode. According to one embodiment, the standby waveform is a waveform with a constant signal value, such as zero.

FIG. 32 illustrates an embodiment of a converter unit 2 that is configured to evaluate the operation mode information included in the synchronization signal S_{v1} and that can be operated in a normal mode or a standby mode. The overall power converter circuit 1 is in the normal mode when each of the converter units 2 is in the normal mode and is in the standby mode when each of the converter units is in the standby mode 2. The converter unit 2 shown in FIG. 32 is based on the converter units of FIGS. 5, 11 and 26, where the DC/DC converter 6 and its control circuit 7, and the signal generator 20 are optional. The converter unit 2 includes an operation mode unit 30 that receives the synchronization signal S_{v1} and that is configured to evaluate the synchronization signal S_{v1} . The operation mode unit 30 is, in particular, configured to detect a change of the synchronization signal S_{v1} from the standby waveform to the normal waveform, the latter being the usual waveform in the normal mode. Referring to the explanation above, the normal waveform can be a continuous AC waveform, a pulsed signal waveform, or an AC waveform with only periods.

The operation mode unit 30 is further configured to control the DC/AC converter 4, in particular to activate the DC/AC converter 4 in the normal mode and to deactivate the DC/AC converter in the standby mode. When the converter unit 2 further includes the DC/DC converter 6, the operation mode unit 30 further controls the operation (activates or deactivates) of the DC/DC converter 6. When the DC/AC converter 4 and the optional DC/DC converter 6 is activated, the operating principle of the converter unit 2 corresponds to the operating principle explained before, which means the converter unit 2 provides an output current $i1$ in accordance with the synchronizations signal S_{v1} . When the DC/AC converter 4 and the optional DC/DC converter 6 are deac-

30

tivated, the switches (see FIGS. 6 and 19) in the DC/AC converter 4 and the DC/DC converter are either switched off, or some of the switches are permanently switched on. This is explained in greater detail below.

In the standby mode, the operation mode controller 50 either disconnects the series circuit 2₁-2_n from the output terminals 11, 12 and, therefore, from the external AC voltage v_1 , or leaves the series circuit 2₁-2_n connected to the output terminals 11, 12.

Embodiments of start-up sequences for switching from the standby mode to the normal mode are explained below. For explanation purposes it is assumed that the individual DC power sources are PV modules. In this case, a start-up sequences is required at least once a day, namely in the morning after sunrise.

A first embodiment of a start-up sequence (start-up sequence A) is illustrated in FIG. 33. In this embodiment, the individual converter units 2 in the standby mode 902 are configured to pass the input voltage $V3$ from the input terminals 21, 22 through to the output terminals 23, 24, and the operation mode controller 50 is configured to have the connection circuit 70 disconnect the series circuit 2₁-2_n from the output terminals 11, 12.

The input voltage $V3$ can be connected through the converter unit 2 to the output terminals 23, 24 by switching on switches in the DC/AC converter 4 and the optional DC/DC converter 6 in a specific configuration. When, for example, the DC/AC converter 4 is implemented with a H4-bridge as illustrated in FIG. 6, the input voltage $V3$ can be connected through to the output terminals 23, 24 by permanently switching on the first switch 421 and the fourth switch 424. When the optional DC/DC converter 6 is a boost converter, as illustrated in FIG. 12, the switch 65 is permanently switched off, and when the optional DC/DC converter 6 is a buck converter, as illustrated in FIG. 14, the switch 65 is permanently switched on. The switching states of the switches in the DC/AC converter 4 and the DC/DC converter 6 in the standby mode is governed by the operation mode unit 30.

When, for example, the DC/AC converter is implemented with a buck converter and an unfolding bridge as illustrated in FIG. 19, the input voltage $V3$ can be connected through to the output terminals 23, 24 by permanently switching on the first switch 85₁ and the fourth switch 85₄ in the unfolding bridge 85 and by switching on the switch 83 in the buck converter 80.

After sunrise, the input voltage $V3$ at the input terminals 21, 22 and, therefore, the output voltage $v2$, which at this stage is a DC voltage, increases. The operation mode controller 50 is configured to detect the output voltage v_{OUT} . The output voltage v_{OUT} is the sum of the output voltages $v2$ of the individual converter units 2, where this output voltage v_{OUT} increases after sunrise when the solar power received by the PV modules increases. When the output voltage v_{OUT} reaches a given threshold voltage v_{OUT-TH} , the operation mode controller 50 controls the synchronization circuit 10 to generate the synchronization signal S_{v1} with the normal waveform has the connection circuit 70 connect the series circuit 2₁-2_n to the output terminals 11, 12. Referring to the explanation before, the synchronization signal S_{v1} in a normal mode can be a continuous AC signal, a periodic pulse signal, or an AC signal for a limited time duration.

The operation mode unit 30 detects the change of the synchronization signal S_{v1} from the standby level to the normal level. The operation mode unit 30 then activates the DC/AC converter 4 and the optional DC/DC converter 6 to operate as explained with reference to FIGS. 1 to 23 before.

31

According to one embodiment, the DC/AC converter 4 and the optional DC/DC converter 6 are activated at the time of a zero crossing of the synchronization signal S_{v1} , so as to ramp up the output current $i1$.

According to one embodiment, not only frequency and phase of the output current $i1$, but also the amplitude of the output current $i1$ is controlled during the start-up phase so as to, e.g., continuously increase the output current in the start-up phase. The output current $i1$ of each converter 2 can be controlled by controlling the input power of the converter 2. Controlling the input power is possible in each converter topology in which the input voltage $V3$ is controlled, that is in each topology where the input voltage $V3$ is adjusted dependent on an input voltage reference signal S_{V3-REF} . In the normal mode, the input voltage reference signal S_{V3-REF} may be generated by an MPP tracker (see, circuit block 7 in FIGS. 11 and 32) that serves to operate PV modules 3 providing the input voltage $V3$ in an optimum operation point. In order to control the input voltage $V3$ and, therefore, in order to control the output current $i1$ during start-up, the operation mode control circuit 30 can be configured to provide the input voltage reference signal S_{REF-V3} during start-up or can be configured to control the MPP tracker 7 during start-up. This is schematically illustrated in dotted lines in FIG. 32. During the start-up phase, the PV modules 3 are not necessarily operated in their MPP. According to one embodiment, the operation mode control circuit 30 increases the input voltage reference signal S_{REF-V3} stepwise in two, three or more steps, so as to stepwise increase the amplitude of the AC output current $i1$ of the individual converter units 2.

When in the converter unit 2 of FIG. 32, the DC/AC converter 4 includes a buck converter 80 and an H4-bridge 85, as illustrated in FIG. 19, the buck converter 80 can be configured to control the input voltage $V3$. The DC/DC converter 6 may be omitted in this case. An embodiment of a control circuit 5 that is configured to control the input voltage $V3$ in the DC/AC converter 4 of FIG. 19 is illustrated in FIG. 22. While in the normal mode, the input voltage reference signal S_{V3-REF} is provided by an MPP tracker (not illustrated in FIGS. 19 and 22), the input voltage reference signal S_{V3-REF} may be provided by the operation mode unit 30 during the start-up phase in order to control the output current $i1$ during the start-up phase.

Switching on the switches in the DC/AC converter 4 and the optional DC/DC converter 6 in the standby mode requires a power supply. Referring to FIG. 32, each converter unit 2 includes a power supply unit 40 that provides for the power supply of the individual components in the converter unit 2. The power supply unit 40 is either connected to the input terminals 21, 22, to the output terminals 23, 24 or, when there is a DC link capacitor between the DC/DC converter 6 and the DC/AC converter 4, to the DC link capacitor.

When the power supply unit 40 is connected to the input terminals 21, 22, energy for switching on the switches in the DC/AC converter 4 and the DC/DC converter 6 is, of course, only provided when an input voltage $V3$ other than zero is provided by the DC power source. Thus, after sunrise, the input voltage $V3$ first powers the power supply unit 40, which powers the components in the power converter unit 2, which then passes the input voltage $V3$ through to the output terminals 23, 24, the output voltage $v2$ is then detected by the operation mode controller 50, which then has the converter unit 2 change to the normal mode by having the synchronization circuit 10 change the synchronization signal S_{v1} from the standby waveform to the normal waveform.

32

Before solar power is provided to the PV modules, i.e. when the input voltage $V3$ is zero, each of the switches in the converter unit 2 is switched off and the converter unit cannot be activated. This operation mode can be referred to as shut-off mode.

Start-Up Sequence B

A second embodiment of a start-up sequence (start-up sequence B) is illustrated in FIG. 34. In this embodiment, the operation mode controller 50 leaves the series circuit 2₁-2_n connected to the output terminals 11, 12 when the power converter circuit 1 is in the standby mode. The individual converter units 2 are deactivated, so that the output current i_{OUT} is zero and the output voltage v_{OUT} corresponds to the external AC voltage v_1 . The external AC voltage v_1 charges the input capacitor of the DC/AC converter 4, which is the DC link capacitor when a DC/DC converter 6 and a DC/AC converter 4 are employed. The charging of the input capacitor of the DC/AC converter 4 is explained for the DC/AC converter topologies of FIGS. 6 and 19 below. Referring to FIG. 6, the switches of the H4-bridge each have a freewheeling element 42₁-42₄. Via these freewheeling elements the input capacitor 41 (or the DC link capacitor 60 of FIG. 11) is charged to the peak value of the AC voltage $v2$ between the output terminals 23, 24, when the switches 42₁-42₄ are switched off. Thus, in the standby mode, the operation mode unit (30 in FIG. 32) controls the switches of a DC/AC converter 4 implemented with a H4-bridge to be switched off.

When the DC/AC converter 4 is implemented with an unfolding bridge 85 as illustrated in FIG. 19, the DC link capacitor 89 is charged through freewheeling elements (not illustrated in FIG. 19) of the individual switched 85₁-85₄ to the peak value of the AC input voltage $v2$.

In this embodiment, the power supply unit 40 is connected to the input capacitor of the DC/AC converter 4 or to the DC link capacitor which permanently provides for a power supply of the converter unit 2.

While in the start-up sequence A the power converter automatically enters the normal mode when sufficiently high input voltages $V3$ are provided, an additional trigger signal is required in the start-up sequence B informing the operation mode controller 50 that the power converter circuit 1 may switch from the standby mode to the normal operation mode. According to one embodiment, the trigger signal is a signal indicating the sunrise and, therefore the time when enough solar power is expected to be received by the individual PV modules in order to successfully switch from the standby mode to the normal mode. This trigger signal can be provided from an external source to the operation mode controller 50 or can be calculated in the operation mode controller 50 dependent on the specific date, the geographical position of the PV modules and a table that includes the time of sunrise at the geographical position at different dates. This signal triggering a switching from the standby mode to the normal mode will be referred to as trigger signal or sunrise signal in the following.

Start-Up Sequence C

According to a further embodiment (start-up sequence C), which includes features from both, the start-up sequences A and B, the operation mode controller 50 leaves the series circuit 2₁-2_n disconnected from the output terminals 11, 12 in the standby mode. Further, the converter units 2 are configured to pass through the input voltage $V3$ to the output terminals 23, 24 in the standby mode. In this embodiment, switching of the power converter circuit 1 from the standby mode to the normal mode is initiated by the sunrise signal. Again, switching from the standby mode to the normal mode

includes changing the waveform of the synchronization signal S_{v1} from the standby waveform to the normal waveform.

There may be several reasons for the power converter circuit 1 to switch from the normal mode to the standby mode. According to one embodiment, the operation mode controller 50 is also configured to cause the power converter circuit 1 to switch from the normal mode to the standby mode when the operation mode controller 50 detects the occurrence of a shut-down condition. A shut-down information can be transmitted from the operation mode controller 50 to the individual converter units 2 in different ways. When a shut down information is received by the individual converter units 2, the converter units are deactivated and enter the standby mode.

As explained above in connection with start-up sequence I, the operation mode controller 50 can be configured to only start-up the power converter circuit 1 when the output voltage v_{OUT} in the standby mode is higher than a given reference voltage. When the output voltage v_{OUT} is too low, this may have several reasons: First, the solar power received by the PV modules can be too low. Second, there are not enough converter units 2 connected in series.

Transmission of Shut-Down Information I

According to a first embodiment, the synchronization signal S_{v1} is used to transmit a shut-down information from the operation mode controller 50 to the individual converter units 2. Independent of the waveform of the synchronization signal S_{v1} in the normal mode, the operation mode controller 50 simply controls the synchronization circuit 10 to generate a standby waveform of the synchronization signal S_{v1} . The operation mode units 30 in the individual converter 2 are configured to detect the standby waveform and to deactivate the corresponding converter unit upon detection of the standby waveform. In the standby mode, the output currents i_1 of the individual converter units 2 become zero.

Transmission of Shut-Down Information II

According to a further embodiment, the operation mode controller 50 has the connection circuit 70 to disconnect the series circuit from the output terminals 11, 12 when a switching from the normal mode to the shut-off mode is desired. When the series circuit 2_{1-2_n} is disconnected from the power grid and when the converter units 2 are still in the normal mode, the output current provided by each converter unit 2 causes the output voltages v_2 of the individual converter units 2 to increase, so that the overall output voltage v_{OUT} increases. In this embodiment, the converter units 2, are configured to detect their output voltage v_2 and are configured to enter the standby mode when the output voltage increases to an overvoltage threshold. According to one embodiment, the operation mode unit 30 of each converter unit 2 monitors the output voltage v_2 and compares the output voltage with the overvoltage threshold and shuts down the converter unit 2 when the output voltage v_2 reaches the overvoltage threshold. According to one embodiment, the overvoltage threshold is chosen to be dependent on the voltage blocking capability of the semiconductor switches employed in the DC/AC converter 4 of each converter unit 2.

In this embodiment, there is no direct transmission of information from the operation mode controller 50 to the individual converter units 2. Instead, the switching information is provided by allowing the output voltages v_2 of the individual converter units 2 to increase to the overvoltage threshold.

Also in those cases in which the synchronization signal is used to transmit the switching information, so that there is

no intended overvoltage in the individual converter units 2, an overvoltage of the output voltages of one converter unit 2 may occur, e.g., when disconnecting the series circuit 2_{1-2_n} from the power grid. Thus, an overvoltage protection may be implemented in the individual converter units 2 in each case.

Some embodiments of shut-down conditions (errors) that can be detected by the operation mode controller are explained below. Dependent on the type of error, the operation mode controller 50 may try to restart the power converter circuit 1 after a certain time, or may keep the power converter circuit shut down.

Low Output Current

According to one embodiment, the power converter circuit switches from the normal mode to the standby mode, when the output current falls below a given current threshold. This transfer is initiated by the operation mode controller 50 that compares the output current i_{OUT} based on information received from the measurement unit 60 with the current threshold. The current threshold is, for example, chosen from a range of between 0.2 A and 0.5 A.

Undervoltage Condition

Another type of error may occur when the solar power received by each of the converter units 2 is low. In this case, the output current i_{OUT} of the series circuit with the individual converter units 2 may have a non-sinusoidal waveform such that the waveform of the output current i_{OUT} follows the waveform of the external AC voltage v_1 when the instantaneous value of the output voltage v_1 is low, and that the output current i_{OUT} is kept on a constant value or even decreases at higher instantaneous values of the output current. This type of error can be detected by the operation mode controller 50 by comparing the waveform of the output voltage v_{OUT} or the external AC voltage v_1 , respectively, and the output current i_{OUT} . When this type of error is detected by the operation mode controller 50, the operation mode controller 50 initiates one of the shut-down sequences explained above in order to switch the power converter circuit 1 into the standby mode.

Phase Difference

According to a further embodiment, the operation mode controller 50 is configured to measure a phase difference between a phase of the external AC voltage v_1 and the output current i_{OUT} . When this phase difference is larger than a desired phase difference, namely the phase difference given by the synchronization signal S_{v1} v_1 and/or the phase difference as defined by the phase signals S_ϕ , two different courses of action initiated by the operation mode controller 50 are possible. When, for example, the phase difference between the output voltage i_{OUT} and the external AC voltage v_1 is below a first phase difference threshold, the phase difference of the synchronization signal S_{v1} relative to the external AC voltage v_1 can be changed in order to readjust the phase difference between the output current i_{OUT} and the external AC voltage v_1 . When, however, the phase difference is above the phase-difference threshold, the operation mode controller 50 may shut down the power converter circuit 1 using one of the shut-down sequences explained before.

Sunset

Similar to having the power converter start-up using a trigger signal at sunrise, a corresponding trigger signal can be used to shut-down the power converter circuit at sunset.

Automatic Shut Down

When, for example, the solar power received by some of the PV modules is much lower than the solar power received by other modules, the output voltage of the converter units 2 connected to the PV modules receiving a low solar power

decreases, while the output voltage of the other converter units **2** increases. This mechanism has been explained in detail herein before. When there are several PV modules that receive a significantly lower solar power than other modules, the external AC voltage v_1 applied to the output terminals **11**, **12** may result in an overvoltage at the outputs of the other converter units **2**. The converter units **2** having an overvoltage may shut down, which results in an overvoltage at the outputs of other converter units **2**, which are then shut down. This proceeds, until each of the converter units **2** is shut down. When the converter units **2** are shut down, the output current becomes zero. In this case, the individual converter units **2** automatically shut down, so that no shut-down information has to be transmitted from the operation mode controller **50** to the individual converter units **2**. A decrease of the output current to zero is detected by the operation mode controller **50** which may then cause the synchronization circuit **10** to generate a standby waveform of the synchronization signal S_{v1} .

The operation mode controller **50** may not only be configured to monitor the operation of the power converter circuit **1**, but may also be configured to monitor the power grid, specifically the external AC voltage v_1 , in order to shut down the power converter circuit **1** when an error is detected.

Anti-Islanding

A first type of grid error that may occur is "islanding". In this case, the power grid has a high input impedance at the input terminals **7**, **12**. This error can be detected by having the series circuit with the converter units **2** generate a constant output current i_{OUT} or an AC output current i_{OUT} with a frequency that is different from the frequency of the external AC voltage v_1 . As explained hereinbefore, the frequency of the output current i_{OUT} (which is zero, when the output current i_{OUT} is constant) can be adjusted through the synchronization signal S_{v1} .

In order to test for the occurrence of an islanding error, the operation mode controller **50** can be configured to have the synchronization circuit **10** generate the synchronization signal with a frequency other than the frequency of the external AC voltage v_1 . In a test mode in which the operation mode controller **50** changes the output current i_{OUT} as explained before, the operation mode controller **50** compares the waveform of the output current i_{OUT} with the waveform of the external voltage v_1 available at the output terminals **11**, **12**. When the waveform of the external voltage v_1 follows the waveform of the output current i_{OUT} , the power grid has a high input impedance (or has even been switched off distant to the output terminals **11**, **12**). In this case, the operation mode controller shuts down the power converter circuit **1**.

Interruption of Grid Voltage

According to one embodiment, the operation mode controller **50** is configured to monitor the external AC voltage v_1 and is configured to shut down the power converter circuit **1** when the external AC voltage v_1 is switched off or interrupted.

Fault Ride Through

According to one embodiment, the operation mode controller **50** does not shut down the power converter circuit **1** immediately when the external AC voltage v_1 is interrupted, but has the series circuit generate an AC output current i_{OUT} for a specified time period, such as, for example, several milliseconds (ms). The operation mode controller **1** shuts down the power converter circuit **1** when the external AC voltage v_1 has not recovered after this specified time period. The operation mode in which an AC output current i_{OUT} is

provided although the external AC voltage v_1 has been interrupted, is out phase, lower than usual, distorted, short-circuited, etc., is referred to as "fault ride through".

In the fault-ride-through mode, the synchronization information in accordance to which the individual converter units **2** generate their output currents i_1 can be provided in different ways. An embodiment, in which the synchronization information is only transmitted at the beginning of the normal mode and in which a continuous synchronization signal is generated (in the signal generator **20**) in the individual converter units **2**, no additional synchronization information needs to be provided in the fault-ride-through mode. When, however, the individual converter units **2** require a continuous synchronization signal, and when the synchronization signal in the normal mode is generated from the external AC voltage v_1 , the synchronization circuit **10** in the fault-ride-through mode continuous to generate a continuous synchronization signal based on the frequency and phase information of the synchronization signal generated before in the normal mode, i.e. before an interruption of the external AC voltage v_1 has been detected.

Reactive Power Generation

The power converter circuit **1** may even be used to stabilize the voltage on the power grid.

Referring to the explanation provided before, in the normal mode, the output current i_{OUT} generated by the series circuit of the individual converter units **2** has a frequency and a phase as defined by the synchronization signal S_{v1} . The frequency and the phase of the synchronization signal S_{v1} can be adjusted by the operation mode controller **50**. In the normal mode, the synchronization signal S_{v1} is usually generated such that the frequency information included in the synchronization signal S_{v1} corresponds to the frequency of the external AC voltage v_1 and the phase information corresponds to the phase of the external AC voltage v_1 . In this case, the output current i_{OUT} is in phase with the external AC voltage v_1 .

However, there may be situations in which it is desired to have a phase difference between the output current i_{OUT} and the external AC voltage v_1 , in order to provide reactive power to the power grid so as to stabilize the voltage on the power grid. This phase difference can easily be adjusted by suitably adjusting the phase information included in the synchronization signal S_{v1} . According to one embodiment, the operation mode controller **50** receives an external signal from a utility provider, where this external signal includes a desired phase difference between the output current i_{OUT} and the external voltage v_1 . The external signal can be provided to the operation mode controller via conventional communication channels, such as radio channels, power lines, or the internet.

According to a further embodiment, the operation mode controller **50** measures the output power provided by the power converter circuit **1** to the power grid and adjusts the phase difference between the output current i_{OUT} and the external AC voltage v_1 dependent on the output power. According to one embodiment, the phase difference increases, so as to increase the reactive power provided to the net, when the output power provided by the power converter circuit **1** increases.

Active Power Derating

According to a further embodiment, the operation mode controller **50** is configured to detect the frequency of the external AC voltage and is configured to reduce the output power of the power converter circuit **1** when the frequency reaches a frequency threshold such as 50.2 Hz or 60.3 Hz that is above a set value, such as 50 Hz or 60 Hz. The

37

frequency of a grid voltage may increase when there is more power input to the grid than there is power consumed by consumers connected to the grid.

The output power of the power converter circuit 1 can be controlled by controlling the input voltages V3 of the individual converter units 2. This has been explained in connection with “start-up sequence A” before. The information that a reduction of the output power of the individual converter units 2 is required, may be transmitted from the operation mode controller 50 to the individual converter units 2 through the same channel through which the synchronization signal S_{v1} is transmitted.

Restart

Referring to the explanation above, there may be operation scenarios when the power converter circuit 1 is shut down after an error has occurred. After the power converter circuit 1 has been shut down the power converter circuit can be restarted using one of the start-up sequences explained herein before. In the following, “to restart” the power converter circuit 1 means to employ one of the start-up sequences to again start the power converter circuit 1.

When, e.g., the power converter circuit 1 has been shut down due to an error of the power grid, the operation mode controller 50 can be configured to check the external AC voltage v1 and can be configured to restart the power converter circuit 1 after the grid voltage v1 has returned to normal. The operation mode controller 50 may be configured to check the grid voltage in regular time intervals, such as every minute, every five minutes, etc.

When, e.g., the power converter circuit 1 has been shut down due to an undervoltage condition, due to automatic shutdown, or due to a phase difference, the operation mode controller may be configured to restart the power converter circuit after a given time period, such as, e.g., one minute, two minutes, etc.

Of course, the occurrence of an error may also be detected during start-up so that it is even possible to shut down the power converter circuit 1 before the normal operation mode has been reached.

Referring to explanation before, the output current i1 of the individual converter units 2 may be increased in accordance with a given time profile during the start-up phase. This current profile may be fixed current profile. According to a further embodiment, the profile of the output current i1 during start-up is limited dependent on the shut-down history, which means dependent on whether the power converter circuit 1 has been shut down due to an error. According to one embodiment the output current is increased slower (in accordance with a shallower current profile) when the power converter circuit 1 has been shut down due to an undervoltage condition, due to automatic shutdown, or due to a phase difference. When the restart fails because an error has occurred during the start-up phase, an even shallower current profile may be applied after the next restart. A “shallower current profile” is a profile in which the current increases slower.

In the embodiments explained before, the synchronization signal S_{v1} is provided by the synchronization circuit 10, where the synchronization circuit 10 is configured to generate the synchronization signal S_{v1} dependent on the external AC voltage v1, e.g., in the normal mode, or independent of the external AC voltage, e.g., when an error has occurred.

According to a further embodiment illustrated in FIG. 35, the synchronization circuit 10 includes synchronization units 10₁, 10₂, 10_n with each synchronization unit 10₁, 10₂, 10_n coupled to the output terminals of one converter unit 2₁, 2₂, 2_n, configured to measure the output voltage v2₁, v2₂,

38

v2_n of the corresponding converter unit 2₁, 2₂, 2_n, to generate a synchronization signal dependent on the measured output voltage and to provide the synchronization signal to the corresponding converter unit 2₁, 2₂, 2_n. According to one embodiment, the individual synchronization signals are proportional to the output voltages v2₁, v2₂, v2_n, so that the individual synchronization units 10₁, 10₂, 10₃ may be implemented as voltage measurement units.

An embodiment of a converter unit 2 that can be used in the power converter circuit 1 of FIG. 35 is illustrated in FIG. 36. The converter unit 2 of FIG. 36 is based on the converter unit 2 explained in detail with reference to FIG. 32. In the converter unit 2 of FIG. 36, the synchronization signal S_{v1} is a voltage measurement signal received by measuring the output voltage v2 of the converter unit 2. The operating principle of the converter unit 2 of FIG. 36 is explained below.

For explanation purposes it is assumed, that the power converter circuit 1 is in the standby mode. In the standby mode, the power converter circuit 1 is connected to the output terminals 11, 12 (see FIG. 35) so that the external AC voltage v1 is applied to the series circuit with the individual converter units 2. In the standby mode, when the output power of the power converter circuit 1 is zero, the output capacitances (C in the converter unit 2 of FIG. 36) of the individual converter units 2 act as a capacitive voltage divider so that the voltages v2 at the outputs of the individual converter units 2 are in phase with the external AC voltage v1. The start-up sequence employed to start up the individual converter units 2 corresponds to start-up sequence B explained before, with the following differences:

At the beginning of the start-up sequence or before the beginning of the start-up sequence, the synchronization signal S_{v1} is provided to the signal generator 20 for a short time period, such as for several periods of the synchronization signal S_{v1} , which at this time is a sinusoidal signal that is in phase with the external AC voltage v1. The signal generator 20 synchronizes to the synchronization signal S_{v1} and then autonomously generates the continuous synchronization signal S_{v1} in the start-up phase and in the normal mode after the start-up phase. The signal generator 20 can be implemented as explained with reference to FIG. 29 before.

Referring to FIG. 36, the operation mode unit 30 may control the time period when the synchronization signal S_{v1} is provided to the signal generator 20. This is schematically illustrated by having a switch 301 connected between the synchronization unit (not shown in FIG. 36) and the signal generator 20, with the switch being controlled by the operation mode unit. However, this serves to illustrate the operating rather than the implementation. Of course, many different means may be employed to provide the synchronization signal S_{v1} that is dependent on the output voltage v2 to the signal generator for a given time period before or at the beginning of the start-up sequence.

In this converter circuit 1, after the converter circuit 1 has entered the normal mode, the operation mode controller 50 may be configured to detect a phase difference between the output current i1 and the external AC voltage and to shut down the converter circuit 1 when the phase difference exceeds a given threshold. The converter circuit 1 may be shut down as explained before in the paragraph TRANSMISSION OF SHUT-DOWN INFORMATION II. The restart mechanism may correspond to one of the restart mechanisms explained before. At a restart after the shutdown, the converter circuit 1 will again be synchronized to the external voltage v1 as explained before.

According to a further embodiment, the operation mode controller 50 provides a phase shift signal, corresponding to the phase shift signal S_ϕ explained before, to control circuits 5 of the individual converter units 2. In this embodiment, the operation mode controller 50 is configured to adapt the phase shift signal S_ϕ when the phase difference between the output current i_{OUT} and the external voltage $v1$ is above a first phase difference threshold and below a second phase difference threshold, in order to prevent a further increase of the phase difference. Further, the operation mode controller 50 is configured to shut down the converter circuit in order to force a restart when a the phase difference is above the second phase difference threshold.

Each of the circuits explained before may be implemented as analog or digital circuit, or as a mixed circuit with analog and digital circuit means. Consequently, the signals explained before may be analog or digital signals. In case of the synchronization signal S_{v1} or $S_{v1'}$, respectively, "continuous synchronization signal" means that the synchronization signal is available in each period of the AC output current $i1$ and has a waveform corresponding to the waveform of the corresponding output current $i1$.

Although various exemplary embodiments of the invention have been disclosed, it will be apparent to those skilled in the art that various changes and modifications can be made which will achieve some of the advantages of the invention without departing from the spirit and scope of the invention. It will be obvious to those reasonably skilled in the art that other components performing the same functions may be suitably substituted. It should be mentioned that features explained with reference to a specific figure may be combined with features of other figures, even in those cases in which this has not explicitly been mentioned. Further, the methods of the invention may be achieved in either all software implementations, using the appropriate processor instructions, or in hybrid implementations that utilize a combination of hardware logic and software logic to achieve the same results. Such modifications to the inventive concept are intended to be covered by the appended claims.

Spatially relative terms such as "under," "below," "lower," "over," "upper," and the like, are used for ease of description to explain the positioning of one element relative to a second element. These terms are intended to encompass different orientations of the device in addition to different orientations than those depicted in the figures. Further, terms such as "first," "second," and the like, are also used to describe various elements, regions, sections, etc., and are also not intended to be limiting. Like terms refer to like elements throughout the description.

As used herein, the terms "having," "containing," "including," "comprising," and the like are open ended terms that indicate the presence of stated elements or features, but do not preclude additional elements or features. The articles "a" "an" and "the" are intended to include the plural as well as the singular, unless the context clearly indicates otherwise.

With the above range of variations and applications in mind, it should be understood that the present invention is not limited by the foregoing description, nor is it limited by the accompanying drawings. Instead, the present invention is limited only by the following claims and their legal equivalents.

It is to be understood that the features of the various embodiments described herein may be combined with each other, unless specifically noted otherwise.

What is claimed is:

1. A power converter circuit, comprising:

output terminals configured to receive an external voltage; and

a series circuit with a plurality of converter units connected between the output terminals of the power converter circuit, each converter unit comprising input terminals configured to be coupled to a DC power source and output terminals configured to provide an output current, wherein at least one converter unit of the plurality of converter units comprises a signal generator configured to receive a synchronization signal and to generate a continuous synchronization signal from the synchronization signal;

wherein the power converter circuit can be operated in a normal operation mode, and

wherein, in the normal operation mode, the at least one converter unit is configured to regulate generation of the output current such that a frequency and/or a phase of the output current are dependent on the continuous synchronization signal.

2. The power converter circuit of claim 1,

wherein the synchronization signal comprises an AC signal, and

wherein the signal generator is configured to receive the synchronization signal for a given time period, is configured to detect a frequency and a phase of the synchronization signal, and is configured to generate the continuous synchronization signal dependent on the detected frequency and phase after the given time period.

3. The power converter circuit of claim 2, wherein the synchronization signal is dependent on a voltage between the output terminals of the at least one converter unit.

4. The power converter circuit of claim 2, wherein the at least one converter unit is configured to generate the output current such that there is a given phase difference between the output current and the continuous synchronization signal.

5. The power converter circuit of claim 1,

wherein the synchronization signal is a pulsed signal comprising a plurality of signal pulses,

wherein the signal generator is configured to generate the continuous synchronization signal with a frequency and a phase dependent on the frequency and the phase of the pulsed signal.

6. The power converter circuit of claim 5, wherein the at least one converter unit is configured to generate the output current such that there is a given phase difference between the output current and the continuous synchronization signal.

7. The power converter circuit of claim 5, further comprising a synchronization circuit configured to receive the external voltage and to generate the synchronization signal dependent on the external voltage.

8. The power converter circuit of claim 7, wherein the synchronization circuit is configured to generate a signal pulse of the synchronization signal each time a positive or a negative zero crossing of the external voltage occurs.

9. The power converter circuit of claim 1, further comprising:

an operation mode controller, configured to detect a shut-down condition and configured to interrupt a connection between the series circuit and the output terminals upon detection of a shut-down condition.

41

10. The power converter circuit of claim 9, wherein the operation mode controller is configured to detect the shut-down condition when at least one of the following conditions is met:

- an output current at the output terminals of the power converter circuit is below a given current threshold;
- a phase difference between the output current at the output terminals of the power converter circuit and an output voltage at the output terminals of the power converter circuit is above a given phase difference threshold; or
- the output voltage falls below a given voltage threshold.

11. The power converter circuit of claim 9,

- wherein the at least one converter unit is configured to generate zero output current when a voltage between the output terminals of the at least one converter unit reaches a given voltage threshold.

12. The power converter circuit of claim 1, wherein the at least one converter unit comprises:

- a DC/AC converter coupled between the input terminals and the output terminals of the at least one converter unit, the DC/AC converter configured to generate the output current with a frequency and phase that is dependent on a first reference signal; and
- a control circuit configured to generate the first reference signal dependent on the synchronization signal and the output current of the at least one converter unit.

13. The power converter circuit of claim 12,

- wherein the DC/AC converter is configured to receive an input voltage, and

- wherein the control circuit is configured to generate the first reference signal dependent on the input voltage.

14. The power converter circuit of claim 12, wherein the at least one converter unit further comprises:

- a DC/DC converter coupled between the input terminals of the at least one converter unit and the DC/AC converter, the DC/DC converter configured to adjust an input voltage between the input terminals and/or an input current at the input terminals dependent on a second reference signal; and
- a reference signal source configured to provide the second reference signal.

42

15. The power converter circuit of claim 14, wherein the reference signal source is implemented as a maximum power point tracker and is configured to generate the second reference signal dependent on the input voltage and the input current of the at least one converter unit.

16. The power converter circuit of claim 14, wherein the DC/DC converter is a boost converter or a buck converter.

17. The power converter circuit of claim 7, comprising: a plurality of series circuits connected in parallel, wherein the series circuit is one of the plurality of series circuits and wherein each series circuit comprises a plurality of converter units connected between the output terminals, and

wherein the converter units of the series circuits are coupled to the synchronization circuit.

18. A power supply system, comprising:

- output terminals configured to receive an external voltage;
- a series circuit with a plurality of converter units connected between the output terminals of the power supply system, each converter unit comprising input terminals and output terminals for providing an output current, wherein at least one converter unit comprises a signal generator configured to receive a synchronization signal and configured to generate a continuous synchronization signal from the synchronization signal; and

a plurality of DC power sources, each DC power source coupled to the input terminals of one of the converter units,

wherein the power supply system can be operated in a normal operation mode, and

wherein, in the normal operation mode, the at least one converter unit is configured to regulate generation of the output current such that a frequency and/or a phase of the output current are dependent on the continuous synchronization signal.

19. The power supply system of claim 18, wherein each DC power source comprises a photovoltaic array with at least one solar cell.

20. The power supply system, of claim 18, wherein each DC power source comprises a fuel cell.
